ABSTRACT

Some women attending General Practices (GPs) are at higher risk of unintended pregnancy (RUIP) and sexually transmitted infections (STI) than others. A clinical prediction rule (CPR) may help target resources using psychosocial questions as an acceptable, effective means of assessment. The aim was to derive a CPR that discriminates women who would benefit from sexual health discussion and intervention.

Participants were recruited to a cross-sectional survey from six GPs in a city in South-East England in 2016. On arrival, female patients aged 16–44 years were invited to complete a questionnaire that addressed psychosocial factors, and the following self-reported outcomes: 2+ sexual partners in the last year (2PP) and RUIP. For each sexual risk, psychosocial questions were retained from logistic regression modelling which best discriminated women at risk using the C-statistic. Sensitivity and specificity were established in consultation with GP staff.

The final sample comprised N = 1238 women. 2PP was predicted by 11 questions including age, binge-drinking weekly, ever having a partner who insulted you often, current smoking, and not cohabiting (C-statistic = 0.83, sensitivity = 73% and specificity = 77%). RUIP was predicted by 5 questions including sexual debut < 16 years, and emergency contraception use in the last 6 months (C-statistic = 0.70, sensitivity = 69% and specificity = 57%).

2PP was better discriminated than RUIP but neither to a clinically-useful degree. The finding that different psychosocial factors predicted each outcome has implications for prevention strategies. Further research should investigate causal links between psychosocial factors and sexual risk.

1. Introduction

In Britain, General Practices (GP) act as the gatekeeper to specialist secondary services, and are staffed by Practice Nurses and General Practitioners (akin to Family Physicians in the United States). In England 58,969,634 people (approximately 90% of the resident population) are currently registered with a GP (NHS Digital, 2018) from whom they can also obtain a range of interventions directly. Britain's sexual health guidance and policy (DH, 2001, 2013) recommends GPs as sites for provision of sexual health interventions. This widens the availability of testing for sexually transmitted infections (STIs) and contraception; to a broad population who are likely to vary in need for those interventions to a greater degree than those attending specialist contraception and sexual health (CASH) services (Cassell et al., 2006). Without an evidence-based means of targeting these interventions to women in GPs, resources may be wasted offering interventions unnecessarily (Fairley, 2016). Opportunities may also be missed to offer STI testing and contraception to high-risk individuals presenting for unrelated problems.

Within CASH clinics, a sexual history is the standard approach to determining appropriate intervention. This is resource-intensive during GP appointments for unrelated concerns and may feel unacceptable to some GP attenders (Edelman et al., 2013; Define, 2008), leading to possible under-report (DiClemente, 2016). Guidance recommends STI screening in GP settings only for target populations such as men who have sex with men, and for symptomatic individuals. The absence of

| How old are you? | • 15 years or less  
• Between 16 and 24 years  
• Between 25 and 34 years  
• Between 35 and 44 years  
• 45 years or older | Natsal-3 wording, categories developed by authors |
| Thinking about where you are living now, which statement best describes your circumstances? | • I am renting or living rent-free (including living with parents or staying with friends)  
• I own my own home (including mortgage, shared ownership or bought outright) | Natsal-3 response options with different piloted question wording |
| Did you live more or less continuously with both of your natural (birth parents) at home until you were 14? | • Yes  
• No  
• Prefer not to answer | Natsal-3 with underline instead of lengthy explanatory text |
| How often is each of the following kinds of support available to you if you need it: Someone to help if you're confined to bed  
Someone to take you to the doctor if you need it  
Someone to prepare your meals if you're unable to do it yourself  
Someone to help with daily chores if you're sick  
Someone to take you to the doctor if you need it | • None of the time  
• A little of the time  
• Some of the time  
• Most of the time  
• All of the time | Canadian Community Health Survey (systematic review) |
| To what extent is the statement 'I have high self-esteem’ true for you | • Very true of me  
• Somewhat true of me  
• Neither untrue nor true of me  
• Somewhat untrue of me  
• Not very true of me | Robins' Single Item Self-Esteem Scale (SISE) |
| In the last 12 months have you received treatment from a health professional for depression? | • Yes  
• No  
• Prefer not to answer | Natsal-3 with slightly adapted wording (as this was presented in a card) |
| How strongly do you agree with the statement ‘Having a partner at all times is important to me’? | • Strongly agree  
• Agree  
• Disagree  
• Strongly disagree | Atlanta Centre for Disease Control (CDC) study |
| How often do you have 6 or more units of alcohol on one occasion? | • Daily or almost daily  
• Weekly or almost weekly  
• Monthly  
• Less than monthly  
• Never  
• Prefer not to answer | Natsal-3 (also an item in the validated Fast Alcohol Screening Test) |
| Do you smoke cigarettes at all nowadays? | • Yes I smoke cigarettes or roll-ups  
• Yes I smoke e-cigarettes  
• No  
• Prefer not to answer | Natsal-3 with additional e-cigarette category developed following PPI |
| Have you ever taken any non-prescribed, illicit or illegal drugs, including legal highs? | • Yes  
• No  
• Don't know  
• Prefer not to answer | Natsal-3 with wording adapted to specify that legal highs included following PPI |
| At present are you… | • Living as a couple with a partner or spouse  
• In a steady relationship but not living together  
• In a casual relationship  
• Single  
• Prefer not to answer | Natsal-3 |
| Please rate how emotionally satisfying your current relationship is, or how emotionally satisfying you most recent relationship was if you are currently single | • Extremely satisfying  
• Very satisfying  
• Moderately satisfying  
• Slightly satisfying  
• Not at all satisfying  
• Prefer not to answer | Testa et al., 2005 (not systematic review) |
| Please indicate how strongly you agree with the following statement: My partner tells me who I can spend time with  
My partner does what he wants even if I don’t want him to | • Strongly agree  
• Agree  
• Disagree  
• Strongly disagree  
• Prefer not to answer | Atlanta CDC study |
| During your current or most recent relationship did your partner ever have sexual intercourse with anyone besides you | • No definitely not  
• I don't think so  
• It’s quite likely  
• Yes, definitely  
• Prefer not to answer | Testa et al., 2005 (not systematic review) |
| Have you ever been in a relationship with a partner who… Insulted or talked down to you often?  
Shouted or swore at you often?  
Threatened you with harm sometimes?  
Physically hurt you sometimes? | • Yes  
• No  
• Prefer not to answer | HITS domestic violence tool (GP in place of Australian Women’s Health Survey tool in systematic review) |

(continued on next page)
Clinical prediction rules (CPRs) identify risk of current or future adverse outcomes in individuals (Armstrong and Eborall, 2012) using several patient characteristics (Falasinnu et al., 2014a), to inform decisions about whether to offer interventions (Adams and Leveson, 2015). Many existing sexual health risk assessment tools and risk scores are CPRs (Falasinnu et al., 2014b). Most comprise sexual behavioural and socio-demographic ‘known factors’ (Haukoos et al., 2012; Gaydos et al., 2015) and focus on STI risk (Falasinnu et al., 2014b). However, no CPRs have been developed to identify women at risk of STIs and/or risk of unintended pregnancy (RUIP) in primary care, and few have used psychosocial questions for inclusion in the survey questionnaire from a variety of sources based on the preliminary studies (Edelman et al., 2015;Edelman et al., 2017;Robins et al., 1998). These are listed in full in Table 1, and included questions on age group and housing tenure (renting or living rent-free versus home ownership) which remained predictive of multiple partnerships after adjustment for psychosocial factors associated with sexual risk in general population surveys of women, which may be usefully deployed as questions in a CPR for women attending GPs (Edelman et al., 2015;Edelman et al., 2017). That work suggests a psychosocial CPR should focus on identifying women experiencing recent potential risk of:

- STI acquisition through multiple partnerships in the last year (the primary outcome in this study)
- RUIP (desire to avoid pregnancy and not consistently using contraception in last six months)
- STI acquisition (through a potentially infected partner).

The latter outcome was included in the hope of identifying a novel population at risk through their partner’s behaviour (Mittal et al., 2012). Re-infection from the same partner is believed to be a key factor in the re-infection rates for Chlamydia trachomatis, estimated at 20% (cumulative risk) (Walker et al., 2012). Together these outcomes facilitate CPR use for primary prevention (contraception and promotion of condom use) and for secondary prevention (pregnancy and STI testing and treatment).

The aim of this study was to identify the best combination of psychosocial questions to form an acceptable CPR to target sexual health intervention in General Practices to women of reproductive age. To do this we addressed the following research question: What combination of acceptable psychosocial and socio-demographic questions discriminates best those women experiencing multiple partnerships, potential risk of STIs through partner and risk of unintended pregnancy?

2. Methods

We undertook a cross-sectional quantitative survey across GPs in a city in South-East England between April and September 2016. All female GP attendees aged 16–44 years were eligible to participate: we included women who did not report any male sexual partners in the last year so that we could assess the discriminatory power of the CPR.

2.1. Exposures

We identified psychosocial questions for inclusion in the survey questionnaire from a variety of sources based on the findings of preliminary studies (Edelman et al., 2015; Edelman et al., 2017; Robins et al., 2001; Gao and Chen, 2011; Raiford et al., 2009; Testa et al., 2005; Wellings et al., 2015; Sherin et al., 1998). These are listed in full in Table 1, and included questions on age group and housing tenure (renting or living rent-free versus home ownership) which remained predictive of multiple partnerships after adjustment for psychosocial questions in a preliminary study (Edelman et al., 2017). We chose psychosocial items that were brief and had few response options so that they would be easy to self-score and therefore suitable for self-completion in the CPR. We privileged items that were more common to ensure adequate prediction (i.e. applying the rationale that rarer exposures would lead to the identification of fewer women). We added a ‘prefer not to answer’ option to exposures that might be deemed unacceptable in order to measure this.

2.2. Outcomes

We developed a model for each of the following outcomes, which were designed to represent recent histories that would warrant sexual health discussion and possible intervention.

1. Report of 2+ male sexual partners in the last year (2PP) - indicating possible need for sexual health advice and STI testing. This outcome was measured using a single item ‘In the last year, how many men have you had sexual intercourse with? By sexual intercourse we mean a man's penis in a woman's vagina, mouth or anus’.
2. Report of 2PP and/or risk of STI through a male partner (i.e. that the participant perceived that their most recent male sexual partner had had other sexual partners in the last year and had not always used condoms with those other partners).
3. Report of risk of unintended pregnancy in the last six months

| In the last six months have you taken a pregnancy test because you thought you might be pregnant? | • Yes  
• No  
• Prefer not to answer | Adapted from the Contessa study |
(RUIP), indicating a possible need for contraception. At the time of development there was no suitable existing measure. Therefore we constructed a composite measure from an item measuring contraception use (Wellings et al., 2013a) and an item measuring desire to avoid pregnancy (Miller et al., 2013), adapting each to report retrospectively on the last six months.

These outcomes were limited to heterosexual experiences on the basis that women who only have sex with other women are at considerably lower risk for STI acquisition than other women (Everett, 2013). Nonetheless, the exclusion criteria did not incorporate women who self-identified as lesbian, as their exclusion from sexual health research is a growing concern as sexual health moves away from a disease-focused biomedical model (Wellings and Johnson, 2013). In addition, evidence suggests that some women who identify as lesbian may also report recent sexual activity with men (Everett, 2013) and may therefore experience the outcomes of interest.

2.3. Data collection

Data collection was designed to mimic envisaged delivery of the CPR – in which women self-complete and self-score the CPR during a clinic visit using a paper-and-pencil format. Patient and Public Involvement (PPI) was conducted by consultation with women attending a GP, a Women’s Centre and a Youth Forum (who comment on a range of health services and research) to decide this delivery method and finalise the following approach to data collection.

On arrival, women attending GPs were offered an envelope by research or Reception staff, except visibly distressed women, those known to have insufficient English language skills, or those who were clearly outside of the eligible age-range. Each envelope contained a pen, participant information sheet (PIS) and a brief questionnaire, comprising potential CPR items and the outcomes of interest. The questionnaire was designed to take 5 minutes to complete, while awaiting an appointment. This was deemed feasible as a 2016 study of General Practices in the study location found a mean waiting time of 15.6 minutes (K. Maskell, personal communication, November 9, 2017). Participants were instructed to complete the questionnaire anonymously, sitting alone in the waiting area if possible. Consent was implied by completion of the questionnaire. Three questions on the front of the questionnaire were used to screen out ineligible patients (those who had completed the questionnaire previously and/or did not identify as female and/or were outside the eligible age-range) were in-

Exposures reported by < 10% of respondents. We selected which psychosocial variables to enter into each model and then generated three models, one for each of the outcomes listed above. We used backwards-stepwise multivariable logistic regression as an established methodology for CPR derivation (Adams and Leveson, 2012; Falasinnu et al., 2014c; Gotz et al., 2005).

To assess model performance as a potential set of CPR questions, we used the C-statistic to quantify how well the model discriminated between those with, or without, the sexual risk of interest. The amount of variance explained by each model was assessed using McFadden’s pseudo-R squared and calibration using Hosmer-Lemeshow goodness-of-fit test. Bayesian Information Criteria (BIC) were used to compare the parsimony of models. Exposures were not manually removed from the models if the corresponding p-value was > 0.05 as CPR derivation is a process of estimation rather than hypothesis testing. This is a recognised statistical approach to clinical prediction modelling (King et al., 2016). For each finalised model the coefficients were used to generate a scoring system for the CPR (Sullivan et al., 2004). A cumulative CPR score was then calculated for each participant based on their survey responses. For each model, participants’ scores were cross-tabulated against their self-report of that outcome to assess how many participants would be classified as false positive or false negatives using the derived scoring system. Optimal cut-off values for sensitivity and specificity were then selected in a group consultation with five General Practitioners at one of the participating recruitment sites.

A sample size of 1500 was set in order to achieve an anticipated 150 reporting 2PP based on previous analyses (Edelman et al., 2017), sufficient to generate a 10–12 item CPR using the 10 events-per-variable approach (Peduzzi et al., 1996). 2PP was chosen as the primary outcome of interest as a known broad indicator of sexual risk (Sonnenberg et al., 2013). We ceased data collection at n = 1200 when n = 150 reporting 2PP had been exceeded.

3. Results

The final sample comprised n = 1238 women. 21.7% (n = 269) were aged 16–24 years, 41.8% (n = 518) were aged 25–34 years, and 36.4% (n = 451) were aged 35–44 years. 69.4% (n = 859) reported that they were currently renting or living rent-free and 29.7% (n = 368) owned their own home. Fig. 1 presents completion rates. We were unable to estimate response rates or investigate reasons for non-participation. Low rates of missing data and ‘prefer not to answer’ responses indicated that the questions were highly acceptable. Those exposures without the latter category still captured missing data n ≤ 40, comparable with those exposures that did offer a ‘prefer not to answer’ option.

The final model identified for ‘2+ sexual partners in the last year’ comprised 11 items (Table 2). The Variance Inflation Factor of 1.21 indicated no multi-collinearity. Therefore no candidate predictors for this model needed to be removed to avoid inflated standard errors. This generated reasonable discriminatory power of C = 0.83 but low amount of variance explained (McFadden’s Pseudo $R^2 = 0.27$). Good model calibration was indicated by H-L = 5.15 ($p = 0.74$). Although statistical significance is not the primary concern of modelling for estimation purposes (as in this case), the majority of exposures demonstrated an independent statistically-significant association with the outcome modelled. Through GP consultation a cut-off score of nine or above (range = 0–18) was chosen. This afforded a sensitivity of 72.8% and specificity of 76.7%.

The model identified for ‘combined risk through multiple partners or most recent partner’ comprised 11 items (Table 3), similar to those in the model for 2PP. The Variance Inflation Factor was 1.89, therefore no candidate predictors for this model needed to be removed to improve the accuracy of coefficients. It generated reasonable discriminatory power of C = 0.79 but explained only a small amount of the variance in outcome values (McFadden’s Pseudo $R^2 = 0.21$). H-

Our findings demonstrate that a variety of psychosocial variables are associated with sexual risk among GP-attending women of reproductive age. The results indicate that it is possible to discriminate women attending General Practices who report experiencing multiple male partners and/or risk through partners, to a greater degree than those experiencing RUZIP. The findings also suggest that RUZIP is predicted by a different profile of psychosocial factors. However, the findings indicate that our CPR does not warrant further validation and evaluation for routine use in GP settings using the particular psychosocial questions that we tested, because the level of discrimination achieved is unlikely to be practical for decision-making in GP settings.

Interestingly, various tools for related issues are already validated for use in General Practices, and may already be used in practice despite large differences in sensitivity and specificity. For example the HITS (Hurt, Insulted, Threatened with harm, Screamed at) domestic violence screening tool has demonstrated 96% sensitivity and 91% specificity in a General Practice setting (Sherin et al., 1998). The AUDIT-C (Alcohol Use Disorders Identification Test of Consumption) demonstrated sensitivity of 73% and specificity of 91% among women attending General Practice (Bradley et al., 2007). This sensitivity was therefore akin to this CPR. However, the specificity of our CPR was much lower, raising concerns among our stakeholders about its routine use in GP environments. Nonetheless, it is important to note that the specificity of our CPR may be lower in the study than in practice, as women who have been sexually inactive in the last year are likely to decline its use.

Unlike many sexual health tools that are developed without preliminary investigation (Falasinnu et al., 2014b), our CPR included candidate predictor variables selected on the basis of two separate
preliminary studies of random probability surveys (Edelman et al., 2015; Edelman et al., 2017). This survey was conducted on the population for whom the CPR is intended, and in the same setting, using a similar paper-and-pencil self-completion approach. This improves the validity of the dataset and similar paper-and-pencil self-completion approach. This improves the sensitivity and specificity. Similarly, electronic delivery would have allowed for the development of a more complex and potentially more sensitive scoring system, using a larger number of response options.

In order to tailor the CPR towards primary prevention, the outcomes of interest in this study concerned recent sexual behaviour rather than morbidity. Thus, we could not verify self-report using more objective measures. Recall bias may also have occurred in the self-report of both exposures and outcomes, particularly as the study was cross-sectional and several items in the survey were unvalidated.

The study benefited from having a large sample, ensuring sufficient statistical power to undertake multivariable regression. However, using convenience sampling may have resulted in an under-representation of those reporting sexual risk behaviour and adjunct psychosocial issues, such that sample bias cannot be ruled out. Because brevity and self-completion were key concerns, we were unable to record immigrant or other minority status, and the findings may be biased towards those with stronger English language skills and towards those not experiencing current distress. Nonetheless, it is possible that those who were unable or chose not to participate in the study would be equally unlikely to self-complete the CPR in practice so our findings still anticipate the CPR’s performance in practice.

The generalisability of the findings may also be limited by the particular demographics within the city where the study was undertaken. Compared with other geographical areas in the United Kingdom, the population is young, urban, wealthy, University-educated and ethnically homogenous (Brighton and Hove City Council, 2012). A 2016 survey of the city’s General Practices attendees (K. Maskell, personal communication, November 9, 2017) found that 91.6% were White, 87.5% had English as their First Language, 42.4% were educated to degree level, and the mean age was 49.3 years (s.d. = 18.9). Although low sensitivity and specificity suggest that wide-spread delivery of the CPR to all women of reproductive age is not advisable, the CPR may be worthy of further validation and evaluation for targeted use in GP settings to those where poor sexual health is suspected, particularly as a means of generating discussion where adjunct issues such as binge-drinking and intimate partner violence are also a potential cause for concern. In these scenarios the CPR may provide an efficient alternative to clinical decision-making based on either use of socio-demographic data (as a population health approach) or

opportunistic, detailed sexual history (as an individual health approach).

5. Conclusion

Our findings contribute to the broader study of associations between social factors and sexual health. In particular, they indicate that a different set of issues are predictive of RUIP. Further research should take into account how differences in which populations are offered which interventions may affect predictors of sexual risk (e.g. young age may have dropped out of the RUIP model because young women are more likely to be fitted with long acting reversible contraception). Together these findings suggest that further research should be carried out to investigate the role of psychosocial factors both as causal factors in sexual risk and as a means of identifying and differentiating between those experiencing different types of sexual risk.

Funding

This is a summary of independent research funded by the National Institute for Health Research (NIHR)’s Doctoral Research Fellowship programme DRF-2013-06-004. The views expressed are those of the authors and not necessarily those of the NHS, the NIHR or the Department of Health.

Ethical approval

Ethical approval for this study was granted by the University of Sussex and by the National Research Ethics Service Ref 16/LO/0206.

Conflict of interests

There are no conflicts of interests to declare.

Acknowledgements

The authors wish to acknowledge all those who have helped with and contributed to the study. This includes attenders at Brighton Women’s Centre and at Newhaven Youth Forum, the NIHR Clinical Research Network Kent, Surrey and Sussex, the site Principal Investigators: Dr. Jennifer Whetham, Dr. Abbey Gersten and Dr. Paul Deffley; and the staff and patients of all the participating sites: Pavilion Surgery, St Peter’s Medical Centre, Brighton Health and Wellbeing Centre, Charter Medical Centre, Beaconfield Medical Practice and Trinity Medical Centre (formerly Sackville).
