Summary

Background
There is a need for robust, clearly defined, patient-relevant outcome measures for use in randomised trials in perioperative medicine. Our objective was to establish standard outcome measures for post-operative pulmonary complications research.

Methods
A systematic literature search was conducted using MEDLINE, Web of Science, SciELO and the Korean Journal Database. Definitions were extracted from included manuscripts. We then conducted a three-stage Delphi consensus process to select the optimal outcome measures in terms of methodological quality and overall suitability for perioperative trials.

Results
From 2358 records, the full texts of 81 manuscripts were retrieved, of which 45 met the inclusion criteria. We identified three main categories of outcome measure specific to perioperative pulmonary outcomes: 1) composite outcome measures of multiple pulmonary outcomes (27 definitions); 2) pneumonia (12 definitions); and 3) respiratory failure (6 definitions). These were rated by the group according to suitability for routine use. The majority of definitions were given a low score, and many were imprecise and/or difficult to apply consistently in large patient populations. A small number of highly rated definitions were identified as appropriate for widespread use. The group then recommended four outcome measures for future use, including one new definition.

Conclusions
A large number of post-operative pulmonary outcome measures have been used but most are poorly defined. Our four recommended outcome measures include a new definition of post-operative pulmonary complications, incorporating an assessment of severity. These definitions will meet the needs of most clinical effectiveness trials of treatments to improve post-operative pulmonary outcomes.
Introduction

Each year more than 300 million patients undergo surgery worldwide.\(^1\) \(^2\) Estimates of attributable mortality vary from 1 to 4%, however some studies suggest that more than one in five deaths occur in a small group of high-risk patients.\(^1\) \(^3\) \(^6\) Even when complications are successfully treated, these are still associated with reduced long term survival.\(^7\) Some of the most common post-operative complications affect the respiratory tract, with incidences ranging from 9 to 40%, depending on the definition used.\(^8\) \(^11\) A number of factors may promote pulmonary complications amongst patients undergoing major surgery. Anaesthesia can lead to reduced functional residual capacity, hypoxaemia and impaired central respiratory drive, while surgical manipulation can restrict ventilation, damage respiratory muscles and cause atelectasis.\(^12\) When combined with pre-existing respiratory disease and post-operative pain, the risk of pneumonia, respiratory failure and death is increased.\(^10\) There is a need for large, high quality clinical trials to improve the treatment of patients at risk of post-operative pulmonary complications.

The impact of any large clinical trial is critically dependent on the use of well-defined outcome measures, which must be patient-centred, reliable and valid as well as potentially modifiable by the trial intervention.\(^13\) \(^14\) Inconsistent reporting of outcomes across trials investigating similar clinical problems hinders the interpretation of new research findings in the context of existing research evidence, and prevents the use of pooled data in systematic reviews.\(^14\) Many definitions are similar but not sufficiently so to allow robust comparison. There is a recognised need for a standardised list of clearly defined clinical outcome measures for use in large, pragmatic clinical trials in this field.\(^15\) This would help investigators to improve the design of clinical trials through the use of recognised reference standards. This should lead to a stronger evidence base to inform clinical practice and improve short and long-term outcomes for patients after surgery.

The Standardized Endpoints for Perioperative Medicine (StEP) collaboration was established to evaluate the literature and create standards for the definition and use of outcome measures in clinical effectiveness research in perioperative medicine, addressing the need for greater precision and consistency in defining outcomes for perioperative clinical trials.\(^15\) As part of this initiative, we performed a systematic literature review of clinical trials and observational studies of pulmonary outcomes in perioperative care, followed by a Delphi process to develop recommendations for standardised outcomes.
Methods

Members of the group were recruited to better understand and improve the pulmonary morbidity, which occurs during and after surgery. We performed a systematic literature review to identify studies with relevant clinical outcome measures that should be considered for future use in clinical trials. The group then evaluated these outcomes to decide which should be considered as evidence in a wider evaluation of clinical outcome measures in all areas of perioperative medicine.

Search Strategy

MEDLINE, Web of Science, SciELO and the Korean Journal Database were searched electronically from the year 2005 to present using the Web of Science (Thomson Reuters) platform. The search strategy was:

`TS=((Pneumonia[Title/Abstract] OR Respiratory[Title/Abstract] OR Pulmonary[Title/Abstract] OR "Pulmonary Complications"[title/abstract] OR "Respiratory complications"[title/abstract] OR Hypoxia[Title/Abstract] OR "Lower Respiratory Tract"[Title/Abstract] OR Re-Intubation[Title/Abstract] OR "Prolonged Ventilation"[Title/Abstract] OR "Respiratory Failure"[Title/Abstract] OR "Pulmonary Oedema"[Title/Abstract] OR "Respiratory Distress Syndrome"[Title/Abstract] OR "postoperative pulmonary complications"[title/abstract] OR "Acute Lung Injury"[Title/Abstract])) OR ("Lung Injury" OR "Pneumonia" OR "Pulmonary Edema" or "Respiratory Distress Syndrome" OR Pneumothorax OR "Respiratory Aspiration"[MeSH Terms])) AND TS=("Hospital Mortality" OR "Mortality" OR "Morbidity" OR "Prognosis" OR "Perioperative care" OR "Intraoperative Complications" OR "Fatal Outcome" OR "Postoperative Complications" OR "Outcome Assessment Health Care" OR "Outcome and Process Assessment Health Care" OR "Treatment Outcome") AND TS=(Mortality OR Morbidity OR Outcome OR "Postoperative Complications" OR "Prognosis" OR "Perioperative Complications" OR "Intraoperative Complications") AND TS=("Surgical Procedures" OR "Operative" OR "Surgery" OR "General Surgery" OR "Operation") AND "Postoperative Complications"). Search results were limited to those that were observational trials, randomised controlled trials and meta-analyses conducted in adult subjects. The bibliography of evaluable studies and other selected papers were searched manually for potentially relevant citations.

Study selection criteria

Records were held within a record management system (Mendeley, London, UK) and duplicates were removed. The title and abstract of remaining records were then reviewed independently by two researchers (TA and AF). The full text paper of records identified as potentially relevant were downloaded and further assessed. Full texts were selected for inclusion if the study design was that
of an observational study with prospective patient recruitment, a randomised controlled trial or a meta-analysis and reported a respiratory outcome as the primary outcome measure. Articles were excluded if they included paediatric participants (<18 years of age), had a primary outcome unrelated to the respiratory system, or did not provide a primary outcome definition. Differences in opinion were resolved by referral to a third researcher.

**Data Extraction**

Data were extracted from the selected articles by two researchers acting independently. Data was extracted into a database (Excel 2007, Microsoft, USA) and included lead author name, year of publication, number of participants (and papers for meta-analyses), primary outcome measure and definition of primary outcome measure.

**Delphi Process**

The results of this systematic review informed a Delphi consensus process conducted during 2017 to obtain input and consensus from a group of medical and other health researchers with experience in anaesthesia and perioperative medicine trials. The StEP Working Group consisted of experienced perioperative trialists and other investigators from various countries and was overseen by a steering committee (see supplementary online material). Each Delphi round was coordinated by the Health Services Research Centre of the Royal College of Anaesthetists in the UK or the Research Unit of the Department of Anaesthesia and Perioperative Medicine at the Alfred Hospital in Melbourne, Australia. The item scores and number of respondents was recorded for each of the above Delphi rounds in an Excel spreadsheet, and then converted to an SPSS database for calculation of final median and range scores, and consensus rates.

**Stage 1: Literature search to develop preliminary list of trial endpoints and definitions**

Publications identified in the literature search were used to create a preliminary list of outcome measures and their definitions.

**Stage 2: Formal rating of the recommendations (Delphi round one)**

We extracted the outcome measures from manuscripts identified in our literature search, and then created summary tables in different categories, allowing easy comparison of outcome measure definitions. We circulated these tables within the Pulmonary StEP theme group and asked members to submit their ratings via an online form. Manuscripts were first evaluated by using a ‘traffic light’ scale (green / amber / red) for methodological quality, and overall suitability as endpoints in the
context of perioperative trials. This rating encompassed validity, reliability, ease of use, and frequency of use in the perioperative literature. Where two or more alternative definitions were very similar, we promoted use of the more precise and detailed alternative(s). Definitions that had been superseded or were clearly out of date were categorised as red.

**Stage 3: Delphi round two**

The second Delphi round included participants from the entire StEP Working Group (n=75). Participants were asked to score each of the items listed using a scale of 1 to 9, with 1 to 3 labelled “Not that important or invalid”, 4 to 6 labelled “Important but requires revision”, and 7 to 9 labelled “Critical for inclusion”. Participants were given the option to select “unsure” if they were unable to offer an opinion as to which category to apply to the item. Participants were invited to suggest any other endpoints, or definitions, or modifications to existing definitions that they believed should be included. A reminder email was sent to ensure prompt completion of the survey. The final numbers of respondents and item completions were recorded. The number of participants who scored the item and the median, and interquartile range of scores were quantified. Members of the Pulmonary StEP theme group were then invited to discuss the results via email. Any items not rated as critical (i.e., 70th centile score <7) but still with a median score of 7 or greater were retained for consideration in the second round. Lower-rated endpoint items identified for removal could be retained if they were considered as critical by any group member for the second round. Items with a median score of ≤3 were not retained.

**Stage 4: Delphi round three and final recommendations**

Delphi round three included members of the Pulmonary StEP theme group (n=14). The summary results of the above process were provided to these participants, inviting further comments. If responses to this final stage suggested a need for further modification to endpoint definitions, then this was resolved by the authors via email discussion.
Results

Study selection
We identified 2366 records from the electronic search strategy, a further 13 records through other sources. After removal of duplicates, 2358 records remained. The full texts of 81 manuscripts were retrieved, of which 45 met the inclusion criteria (Supplementary figure 1 and Supplementary table 1). A summary of full texts excluded after review, with reason for exclusion, is shown in the supplementary table. The definitions extracted from included studies are summarised in Table 1. We identified three main categories of outcome measure specific to pulmonary outcomes in perioperative medicine 1) composite outcome measures including a number of pulmonary outcomes (27 definitions); 2) pneumonia (12 definitions); 3) respiratory failure (six definitions). These are summarised in Supplementary table 2, tables 1, 2 and 3, along with the rating (red / amber /green) given by the group and a summary definition of each outcome measure.

Post-operative pulmonary complications
Despite a large number of candidate definitions, the group was unable to reach a consensus on the best definition of post-operative pulmonary complications. Many definitions employed component definitions, which differed widely in severity and underlying biological mechanism e.g. atelectasis and Acute Respiratory Distress. After a discussion, and having sought advice from the StEP steering committee, we have recommended a new definition which allows lower severity pulmonary events to be captured as part of the overall clinical outcome (Box 1).

Pneumonia
Only the US Centers for Disease Control definition was recommended. Whilst there are numerous other well-written definitions, there seemed little value in departing from such a widely used international standard (Box 2).

Respiratory failure
The group recommended two definitions covering overlapping patient scenarios. The Berlin definition of Acute Respiratory Distress Syndrome was recommended, again because this is a widely used international standard, which has already been carefully developed in a consensus process. However, as many important episodes of post-operative respiratory failure are not severe enough to meet this definition, the group also recommended an adapted version of a definition reported by Fernandez-Perez, which describes re-institution of mechanical or non-invasive ventilation after extubation (Box 3).
Discussion

We have summarised and evaluated a range of definitions used to describe pulmonary outcomes in perioperative medicine research. Many definitions were imprecise, or difficult to apply consistently in large patient populations because of the requirement from resource intensive diagnostic tests (e.g. bronchoscopy). The composite outcome of post-operative pulmonary complications was widely used, but the group was concerned about the lack of equivalence of component outcomes and the differing biological mechanisms, which may cause these. We therefore propose a new definition for this outcome. Importantly, this new definition includes a measure of severity which we hope will significantly reduce the subjectivity in evaluating pulmonary outcomes, and ensure a more valid comparison between studies. The group also recommended one outcome to describe pneumonia and two outcomes to describe respiratory failure.

The adverse events identified do not represent a comprehensive list of all that may occur. Instead, we have focused on those considered most important in a mixed population of surgical patients and relevant to perioperative care as opposed to specific technical complications of surgery or anaesthesia. In some cases, we did not identify existing research that utilised outcomes that would be considered important. An example is pulmonary thromboembolism, which can only be reliably detected through screening of all participating patients in a given trial. Some outcomes may be more appropriate for use in smaller studies or early phase trials e.g. Clinical Pulmonary Infection Score. As previously noted, the physiological changes that follow surgery and anaesthesia, including the systemic inflammatory response, may result in partial compliance with the criteria for a number of outcome measures, in particular atelectasis. We note that reports relating to perioperative medicine are not easily identified through a literature search because there is no standard approach to the use of MeSH terms by authors of perioperative medicine research articles. There is an argument for creating a new MeSH heading of ‘perioperative medicine’ to ensure that trials in this field are more easily identified.

The strengths of this project include a detailed and extensive systematic literature search followed by a robust three stage Delphi process including a core group of experts in post-operative pulmonary complications as well as the wider StEP group which includes many of the leading international experts in perioperative care research. However, this work is limited by the large number of alternative definitions which have been employed in previous research. In particular, we identified a large number of composite outcomes for post-operative pulmonary complications which included a diverse range of adverse events which differed widely in frequency, severity and biological
mechanism. As a result, the group was unable to make a strong recommendation for this important outcome, and instead we have recommended a new definition which we believe is less prone to methodological bias.

Conclusions

We have summarised and evaluated a wide range of pulmonary outcome measures in perioperative medicine research, most of which were poorly defined. Our four recommended outcome measures include a new definition of post-operative pulmonary complications, incorporating an assessment of severity. Together, these definitions will meet the needs of most clinical effectiveness trials of treatments to improve post-operative pulmonary outcomes, although not every definition will be relevant to every trial. This work represents part of an international initiative to improve the definition and use of outcome measures in clinical effectiveness trials in perioperative medicine. These projects include the recent work by the European Society of Anaesthesiology and European Society of Intensive Care Medicine joint taskforce on perioperative outcome measures,\textsuperscript{20} and the Core Outcome Measures in Perioperative and Anaesthetic Care (COMPAC) project which is part of the Core Outcome Measures in Effectiveness Trials (COMET) initiative.\textsuperscript{23}

Box 2. Recommended definition of post-operative pneumonia.

**US Centers for Disease Control definition of pneumonia**

Two or more serial chest radiographs with at least one of the following (one radiograph is sufficient for patients with no underlying pulmonary or cardiac disease):

(1) New or progressive and persistent infiltrates (2) consolidation (3) cavitation; AND at least one of the following:

1. fever (>38°C) with no other recognised cause
2. leucopaenia (white cell count <4 x 10^9 L^-1) or leucocytosis (white cell count >12 x10^9 L^-1)
3. for adults >70 years old, altered mental status with no other recognised cause;

AND at least two of the following:

1. new onset of purulent sputum or change in character of sputum, or increased respiratory secretions, or increased suctioning requirements
2. new onset or worsening cough, or dyspnoea, or tachypnoea
3. rales or bronchial breath sounds
4. worsening gas exchange (hypoxaemia, increased oxygen requirement, increased ventilator demand)
Box 3. Recommended definition of post-operative respiratory failure.

**Berlin definition of Respiratory Distress Syndrome**
Timing: Within one week of a known clinical insult or new or worsening respiratory symptoms AND...

Chest imaging: Bilateral opacities not fully explained by effusions, lobar/lung collapse or nodules AND...

Origin of oedema: Respiratory failure not fully explained by cardiac failure or fluid overload (requires objective assessment, e.g. echocardiography, to exclude hydrostatic oedema), AND...

Oxygenation: Mild. $\text{PaO}_2: \text{FiO}_2$ between 26.7 and 40.0 kPa (200–300 mmHg) with PEEP or CPAP ≥5 cmH$_2$O. Moderate. $\text{PaO}_2: \text{FiO}_2$ between 13.3 and 26.6 kPa (100–200 mmHg) with PEEP ≥5 cmH$_2$O. Severe. $\text{PaO}_2: \text{FiO}_2 \leq 13.3$ kPa (100 mmHg) with PEEP ≥5 cmH$_2$O.

**Mechanical ventilation**
The need for endotracheal re-intubation and mechanical ventilation after extubation, and within 30 days after surgery OR mechanical ventilation for more than 24 hours after surgery. The inclusion of non-invasive ventilation may be considered on a study by study basis.

Hodari et al\textsuperscript{36} 
Post-operative Respiratory Outcomes

Respiratory outcomes tracked in NSQIP: re-intubation (placement of an endotracheal tube and mechanical or assisted ventilation due to respiratory or cardiac failure manifested by severe respiratory distress, hypoxia, hypercarbia, or respiratory acidoses within 30 days of surgery); post-operative pneumonia (one of two criteria: Criterion 1: rales or dullness to percussion on physical examination of chest plus: 1) new onset of purulent sputum or change in character of sputum; or 2) organism isolated from blood culture; or 3) isolation of pathogen from specimen obtained by trans-tracheal aspirate, bronchial brushing, or biopsy. Criterion 2: chest x-ray shows new or progressive infiltrate, consolidation, cavitation, or pleural effusion and any of: 1) new onset of purulent sputum or change in character of sputum; or 2) organism isolated from blood culture; or 3) isolation of pathogen from specimen obtained by trans-tracheal aspirate, bronchial brushing, or biopsy; or 4) isolation of virus or detection of viral antigen in respiratory secretions; or 5) diagnostic single antibody titer (immunoglobulin M) or fourfold increase in paired serum samples (immunoglobulin G) for pathogen; or 6) histopathologic evidence of pneumonia); and prolonged ventilation (ventilator-assisted respirations

</tbody>
</table>
Bagyi et al\textsuperscript{55}  
**Pneumonia**
According to American Thoracic Society guidelines by x-ray (new or progressive radiographic infiltrate), new onset of fever >38.0°C, symptoms of coughing with purulent sputum, chest pain and leucocytosis (white blood cell count >10 G/L).

Centers for Disease Control definition\textsuperscript{20}  
**Pneumonia**
Two or more serial chest radiographs with at least one of the following (one radiograph is sufficient for patients with no underlying pulmonary or cardiac disease):
- New or progressive and persistent infiltrates
- Consolidation
- Cavitation; at least one of the following:
  1. Fever (>38\textdegree C) with no other recognised cause
  2. Leucopaenia (white cell count < 4 x 10^9 L\textsuperscript{-1}) or leucocytosis (white cell count >12 x10^9 L\textsuperscript{-1})
  3. For adults >70 years old, altered mental status with no other recognised cause;
And at least two of the following:
- New onset of purulent sputum or change in character of sputum, or increased respiratory secretions, or increased suctioning requirements
- New onset or worsening cough, or dyspnoea, or tachypnoea
- Ales or bronchial breath sounds
- Worsening gas exchange (hypoxaemia, increased oxygen requirement, increased ventilator demand)

Bouza et al\textsuperscript{56}  
**Ventilator associated pneumonia**
Mechanical ventilation for 48 hours when the presence of new and/or progressive pulmonary infiltrates on a chest x-ray plus two or more of: temperature >38.5\textdegree C or <36\textdegree C; leucocytosis (>12x10^9 cells/L); purulent tracheobronchial secretions; or a reduction of PaO\textsubscript{2}/FiO\textsubscript{2} >15% in the last 48 h according to Centers for Disease Control and Prevention definitions. Patients with a clinical pulmonary infection score (CPIS) >6 were also considered to have pneumonia.

Hortal et al\textsuperscript{37}  
**Ventilator associated pneumonia**
New and/or progressive pulmonary infiltrates on chest radiograph in a patient ventilated more than 48 h plus two or more of: fever >38.5\textdegree C or hypothermia <36\textdegree C, leucocytosis >12x10^9/L, purulent tracheobronchial secretions or a reduction of PaO\textsubscript{2}/FiO\textsubscript{2} >15% in the last 48 h according to the Centers for Disease Control (CDC) definitions. We also included as pneumonia, those with a clinical pulmonary infection score (CPIS) >6. Early-onset VAP was defined as occurring within the first 4 days of hospitalization and late-onset VAP as occurring in day 5 or later on. The isolation of one or more microorganisms in significant bacterial count was required to confirm the diagnosis.
