Intramolecular hydride transfer onto arynes: redox-neutral and transition metal-free C(sp³)–H functionalization of amines
Intramolecular hydride transfer onto arynes: redox-neutral and transition metal-free C(sp³)–H functionalization of amines†

Fahima I. M. Idiris,‡ Cécile E. Majesté,‡ Gregory B. Craven and Christopher R. Jones*†

Transition metal-free intramolecular hydride transfer onto arynes is reported for the first time. This unique transformation is utilized in redox-neutral intermolecular α-functionalization reactions of different tertiary amines, generating C(sp³)–C(sp³/sp²/sp) bonds in a single synthetic operation. Deuterium labeling studies support initial cleavage of the α-C–H bond via intramolecular 1,5-hydride transfer onto the aryne, which leads to activation of a range of integrated pronucleophiles and ultimately affords a new approach to cross-dehydrogenative coupling reactions which utilize aryne intermediates.

Introduction

The direct functionalization of C–H bonds offers a wealth of potential benefits to synthetic chemists,¹ with significant progress having been made in recent decades.² Activation of C(sp³)–H bonds α- to heteroatoms is particularly appealing,³ as evidenced by the burgeoning area of cross-dehydrogenative coupling (CDC) reactions,⁴ whereby certain substrates, especially amines, are functionalized using a sacrificial external oxidant and generally in the presence of a transition metal catalyst.⁵ α-Functionalization of amines has also received considerable recent interest through the development of redox-neutral processes⁶ that exploit the propensity of tertiary amines to undergo 1,5-hydride transfer onto a tethered acceptor,⁷ most commonly electron-deficient alkenes (Scheme 1a).⁸⁹ Here, Lewis acid-catalyzed intramolecular hydride transfer results in a zwitterionic intermediate A that cyclizes to generate a new C–C bond. Maulide and co-workers elegantly extended this strategy to develop a redox-triggered approach to the C–H functionalization of cyclic amines (Scheme 1b).¹⁰ 1,5-Hydride transfer onto an aldehyde acceptor – employed as a sacrificial oxidant – resulted in aminal B, which underwent nucleophilic attack upon addition of organometallic reagents.

Given our interest in arylene chemistry,¹¹ we envisioned a related approach to a general α-functionalization of amines that employs amines as internal hydride acceptors for the first time (Scheme 1c). This new transformation would reveal the unique zwitterionic intermediate C, prevented from undergoing intramolecular cyclization due to geometrical constraints. Significantly, zwitterion C contains a highly basic aryl anion that should be capable of activating a pronucleophile (Nu-H) within the reaction mixture,¹² obviating the use of exogenous organometallic reagents in a second operation and rendering the overall process redox-neutral. Finally, the arylene tether would

also operate as a latent N-benzyl protecting group; easily cleaved when desired.

Arynes are versatile reactive intermediates that have experienced a recent resurgence in interest due to the development of precursors that act under mild conditions, such as 2-(trimethylsilyl)aryl triflates and the hexahydro-Diels–Alder reaction of polyalkynes. Despite undergoing myriad additions with an extensive range of nucleophiles, the reaction of arynes with C(sp³)–H bonds via ionic hydride transfer has yet to be realized. Herein we report this new transformation, which has enabled intermolecular α-functionalization of a range of tertiary amines with different carbon-based pronucleophiles, some of which are uncommon in CDC processes due to comparatively high pKa values. Deuterium labeling studies are described which support initial 1,5-hydride transfer onto the aryne, followed by activation of the integrated pronucleophile. Overall this furnishes new C(sp³)–C(sp³/sp²/sp) bonds in a single and operationally simple procedure via aryne-mediated CDC reactions.

Results and discussion

1,2,3,4-Tetrahydroisoquinoline (THIQ) was selected as the donor portion with which to initially evaluate our 1,5-hydride transfer hypothesis due to its biological activity and general synthetic utility. A suitable aryne acceptor was then tethered onto the amine donor using the 2-trimethylsilyl-3-fluoromethanesulfonyl benzaldehyde precursor reported by Smith III and Kim. Acetonitrile was chosen as the initial pronucleophile as it is a common solvent for o-silylaryl triflate reactions and has been reported to undergo deprotonation by aryne-derived aryl anions. Selected optimization experiments, using THIQ scaffold 1 as a test system, are presented in Table 1. Evaluation of common o-silylaryl triflate activators (entries 1–7) identified KF/18-crown-6 and tetrabutylammonium triphenylfluorosilicate (TBAT) as the most promising reagents. The introduction of toluene as a co-solvent (toluene : acetonitrile, 3 : 1 by volume) enabled higher reaction temperatures which led to an increased yield with TBAT (entry 8). Both increasing and decreasing the reaction concentration resulted in lower yields (entries 9 & 10); most significantly at higher concentration due to competitive intermolecular amine arylation. At this stage we found that the

A range of substituted THIQs 1b–i were found to be amenable to the optimized reaction conditions, affording the corresponding C1-cyanomethylated THIQs 2b–i (Scheme 2). Electron-donating substituents such as methoxy (1b) and hydroxy (1c) were excellent substrates, giving high yields of 2b and 2c. It is particularly interesting to note that 6-hydroxy THIQ precursor 2c was tolerated, as it demonstrated that the unprotected phenol did not cause significant quenching of the anion in zwitterionic intermediate C (see Scheme 1c). Halogens (Br, 1d and Cl, 1e) and moderately electron-withdrawing groups (SO₂NMe₂, 1f and CO₂Et–Bu, 1g) were also viable substrates, affording the corresponding products 2d–g in moderate yields; consistent with less hydridic C–H bonds and decreased carboxylation stabilization in comparison to 1a–c. The incorporation of a strongly electron-withdrawing nitro group into the THIQ scaffold (1h) was found to almost completely inhibit hydride transfer, with only traces of 2h observed. Finally, 1-methyl THIQ 1i proved an effective substrate, generating the quaternary cyanomethylated THIQ 2i in a good yield. It is noteworthy that THIQs occupy a privileged position as benchmark substrates in
CDC reactions, affording \( \alpha \)-functionalized products that typically contain an \( N \)-aryl group. In comparison, the THIQs 2 produced here possess a synthetically practical \( N \)-benzyl protecting group.

Having established the feasibility of intramolecular hydride transfer onto arynes with a range of THIQ derivatives, we continued our investigations by varying the structure of the tertiary amine donor. Starting with dihydrophenanthridine derivative 3a, exposure to the established reaction conditions smoothly afforded 4a in 72% yield (Scheme 3). \( \alpha \)-Phenylbenzylamine precursor 3b and \( \alpha \)-methylbenzylamine 3c generated the quaternary products 4b and 4c in 53% and 32% yields respectively. Interestingly, no benzobarrelene products from a potentially competitive intramolecular Diels–Alder pathway were identified. Instead, the increase in conformational flexibility of the tether is proposed to account for the difference in reactivity between 3a and 3b/c.

Pleasingly, hydride transfer was not restricted to benzylic C–H bonds and proved equally effective with precursors 3d–h that each contained tertiary alkyl C–H bonds. Heterocyclic derivatives 2-methyl-piperidine 3d and 2,5-dimethyl-pyrrolidine 3e gave the corresponding \( \alpha \)-quaternary heterocycles 4d and 4e in moderate yields. Similarly, the less conformationally-rigid amines 3f–h also promoted hydride transfer onto arynes, yielding spirocyclic and acyclic C–H functionalized amines, 4f and 4g/h, respectively.

Having applied the principle of aryne-mediated hydride transfer and subsequent co-solvent activation to the \( \alpha \)-cyano-methylation of tertiary amines, we looked at introducing alternative pronucleophiles in this process. Pleasingly, when dimethoxy-THIQ derivative 1b was exposed to the standard reaction conditions, a range of different carbon-based coupling partners were found to be viable co-solvents (Scheme 4). For example, propionitrile, less acidic than acetonitrile (pK\(_a\) = 32.5 in DMSO cf. 31.3 for MeCN),\(^\text{23}\) yielded \( \beta \)-substituted cyanoamine 5b as a 1 : 1 mixture of diastereoisomers in 66% yield. Nitromethane, a more commonly used solvent in CDC reactions due to significantly higher acidity (pK\(_a\) = 17.2 in DMSO),\(^\text{23}\) produced nitromethylated THIQ 6b in a similarly good 70% yield. Interestingly, a more ‘inert’ solvent such as chloroform also operated as a coupling partner, producing trichloromethylated THIQ 7b in 41% yield. It is noteworthy that better yields were obtained here at a lower 9 : 1 DME : Nu-H ratio and no products from dichlorocarbene intermediates were detected. The use of pentafluorobenzene enabled access to new C(sp\(^3\))-C(sp\(^3\)) bond formation (8b) in good yield, illustrating the potential for \( \alpha \)-amino C(sp\(^3\))-H alylation with electron-deficient arenes in the absence of a transition metal catalyst. Lastly, C(sp\(^3\))-C(sp) coupling could be achieved with phenylacetlene, affording 9b in 48% yield; the addition of copper did not improve the outcome.\(^\text{26}\) THIQ derivatives 1a and 1i also proved amenable to these aryne-mediated CDC reactions, affording the corresponding \( \alpha \)-functionalized THIQs in moderate to good yields.\(^\text{27}\)

Finally, we sought to probe our mechanistic hypothesis. Support for an ionic hydride transfer process came from the retention of the cyclopropane rings in amine 4b (see Scheme 3), as it was reasoned that formation of a radical adjacent to nitrogen would result in rapid and irreversible cyclopropane ring-opening. Furthermore, conducting the cyanomethylation of 1a in the presence of a radical scavenger, TEMPO (2.0 equiv.), did not prohibit the reaction. Next we performed a series of deuterium labeling studies, starting with the reaction of THIQ

**Scheme 2** Intramolecular hydride transfer onto arynes with THIQ derivatives. Reaction conditions: amine 1 (1.0 equiv.), KF (2.0 equiv.), 18-crown-6 (2.0 equiv.). DME : CH\(_3\)CN (3 : 1 by volume, 0.01 M), 90 °C, 12 h. Yields of isolated products throughout. \(^\text{2}\)Ratio determined by \(^1\)H NMR spectroscopy.

precursor 1a in acetonitrile-\textit{d}_3 as co-solvent, which resulted in deuterium incorporation solely at the \textit{meta} position of the benzene ring in THIQ 2a-\textit{d}_2 (Scheme 5a). Next, exposure of bisdeuterated precursor 1,1-\textit{d}_2-THIQ 1a-\textit{d}_2 to the reaction conditions afforded the corresponding product of 1,5-deuteride transfer, 2a-\textit{d}_2, with deuterium located at the \textit{ortho} position of the benzene ring (Scheme 5b).\textsuperscript{28} Finally, a competition reaction between an equimolar amount of THIQ precursor 1a and the bisdeuterated isotopologue 1a-\textit{d}_2 supported the intramolecular nature of the hydride transfer, as the monodeuterated crossover products 2a-\textit{Hd} and 2a-\textit{dH} were not observed (Scheme 5c).

Considering the experimental evidence, the following mechanism is proposed (Scheme 6). Treatment of \textit{o}-silylaryl triflate precursor 3 with fluoride reveals an aryne 10 that subsequently undergoes reduction \textit{via} the intramolecular 1,5-hydride transfer of a C–H bond \textit{z}– to nitrogen. The reactive zwitterionic intermediate 11 deprotonates the acetonitrile pronucleophile, which then adds to iminium ion 12 in a Mannich-type reaction to yield \textit{z}-cyanomethylated amine 4.

**Conclusions**

In summary, we have described an intramolecular hydride transfer that uses arynes as acceptor moieties for the first time and exploited this in the development of aryne-mediated CDC reactions of heterocyclic and aliphatic tertiary amines. This is a transition metal-free and redox-neutral process that generates a new C(sp\textsuperscript{3})–C(sp\textsuperscript{3}/sp\textsuperscript{2}/sp) bond \textit{z}– to nitrogen in a single synthetic operation. The approach is distinct from existing...
transition metal-free methods for C–H functionalization via hydride transfer as a Lewis acid is not required to activate the acceptor and intermediate zwiterion cyclization is geometrically inhibited. Furthermore, the highly basic aryl anion directly activates a number of diverse pronucleophiles – some of which are not often encountered in CDC processes due to high pKa values – which enables integration of an intermolecular coupling partner in the same reaction vessel. The reduced aryne tether also operates as a practical coupling partner in the same reaction vessel. The reduced aryne activates a number of diverse pronucleophiles which enables integration of an intermolecular coupling partner in the same reaction vessel.

Notes and references

27 Nitromethyl and trichloromethyl derivatives of 1i could not be isolated, presumably due to dissociation being favoured by the increased stability of the C1-substituted iminium ion and the greater acidity of the corresponding co-solvents.

28 Slower rate of deuterium transfer relative to hydride transfer enables competing and deleterious intermolecular amine arylation, resulting in slightly lower yields of cyanomethylated product 2a-d₂.
