Evaluation of substituted 1,2,3-dithiazoles as inhibitors of the Feline Immunodeficiency Virus (FIV) nucleocapsid protein via a proposed zinc ejection mechanism

Christopher R. M. Asquith[a][b], Lidia S. Konstantinova[c][d], Tuomo Laitinen[e], Marina L. Meli[b], Antti Poso[e], Oleg A. Rakitin[c][d], Regina Hofmann-Lehmann[b], Stephen T. Hilton[a]*

Abstract: A diverse library of 5-thieno-, 5-oxo-, 5-imino-1,2,3-dithiazole derivatives was synthesized and evaluated for efficacy against the Feline Immunodeficiency Virus (FIV) as a model for HIV in cells. Several diverse compounds from this series displayed nanomolar activity and low toxicity, representing a potential new class of compounds for the treatment of FIV and HIV.

Introduction

The continual discovery of novel therapeutics against varying strains of both viruses and bacteria is essential due to their ability to adapt and become resistant to current treatments. The human immune deficiency virus (HIV) is a case in point, with an array of drugs used to target multiple points in the viral life cycle, but the continual development of resistance by the virus has continued to erode their efficacy.1 HIV, which results in the development of Acquired Immunodeficiency Syndrome (AIDS), has caused over 25 million deaths worldwide, with over 34 million people currently infected with HIV.2 Amongst non-primate lentiviruses such as HIV-1 and HIV-2, only the Feline Immunodeficiency Virus (FIV) causes a similar compromised immune system as seen in humans,3 with several FIV strains also displaying central nervous system involvement and analogous AIDS-type disease progression.4,5

The short basic nucleic acid binding nucleocapsid protein (NCP) of HIV and FIV is an under-explored anti-viral target with no clinically used drugs, despite its involvement at multiple points of the viral replication cycle. These include annealing of the cellular primer tRNA36 to the primer binding site in reverse transcription,6,7 promotion of dimerisation, packing and organization of protein-RNA complexes within freshly created virions.8-10 The NCP is an attractive protein target as it has been shown to be mutation resistant with inhibition yielding non-infectious virions.6,11 It contains a conserved double zinc finger peptide unit C-X3-C-X3-H-X3-C (CCHC) that is found in nearly all retroviruses with the exemption of spumaviruses,12 including HIV-1/2,12,13 FIV,14 Simian Immunodeficiency Virus (SIV),15 Equine Infectious Anemia Virus (EIAV),16 amongst others.17 The development of an effective agent that could target one or both of these zinc fingers of the nucleocapsid protein would render the virus inert as deletion or modification of either zinc finger leads to virus inactivation.18,19

Two different approaches have been utilised towards the development of nucleocapsid inhibitors: the first, based on small molecules that compete with the binding of the substrate RNA nucleic acid chain has met with some success.20,21 The second approach based on the irreversible ejection of the structural Zn2+ ion has been more productive. Key compounds with this mechanism of action are exemplified by compounds 1-8,22-29 Common functionalities include a disulphide bridge and more recently a diselenide bridge30 and/or a stable electronically deficient core/functional group(s) (Figure 1).

![Figure 1. Previously reported zinc abstractors in the literature](image)

As part of a longer term program focusing on the development of novel anti FIV/HIV agents that target the NCP via zinc abstraction, exploring the development of novel compound classes. We achieved this using FIV as a surrogate model for HIV; the results of our investigations are reported below.
Results and Discussion

In order to develop novel therapeutic agents against the NCp of FIV, we used an in silico homology model derived from HIV-1 and EIAV nucleocapsid proteins to explore heteroatom rich disulphide containing compounds. Building on our previous knowledge relating to bis[1,2]dithiolopyrimidines and bis[1,2]dithiopyrrole derivatives and tetrahydrothiophene derivatives. The 1,2,3-dithiazole core caught our interest as it has been shown to have a broad biological inhibition profile with activities. These properties include anti-bacterial, anti-cancer, anti-fungal/herbicidal and anti-melanin activities.

The 1,2,3-dithiazole scaffold is a stable and has the potential to be substituted at the C-4 and C-5 positions, while containing an electrophilic disulphide bond. Substitutions were made to explore the propensity of the disulphide to react with the cysteine thiolates of the NCp model. Investigation of the alignment and electronic distribution of the 1,2,3-dithiazole core led to a small selection of structurally diverse compounds, which were computationally modelled using Density Functional Theory (DFT) and a small selection of compounds were then synthesized and tested (Figure 2).

![Figure 2. Virtual screening was based on both molecular docking (left) and DFT molecular orbital calculations (right). Molecular docking was used to estimate if the screened compound is able to achieve a suitable docking pose. The DFT calculations were based on the docking poses and thus validated if the frontier orbitals of the reactants are geometrically optimally located or not (HOMO orbitals marked using a red surface and the LUMO orbitals of blue colored 1,2,3 dithiazole scaffold). (Schrodinger Maestro).](image)

A series of selected 1,2,3-dithiazoles containing a disulphide bridge and our supporting mechanistic rationale demonstrating the potential of this heterocyclic system. These heterocycles pose under-reported in the literature, due to the fact that C-5 substituted derivatives are a relative synthetic challenge.

To date, 1,2,3-dithiazole chemistry has centered around the 4,5-dichloro-1,2,3-dithiazolium chloride salt (Appel Salt) and the susceptibility of attack by nucleophiles at the S-1, S-2, C-4 and C-5 atoms. We anticipated that these synthetic mechanisms to access the core could also potentially play a part in the zinc abstraction mechanism. Although a C-5 chloride substitution is more commonly reported with the Appel salt chemistry, this could present an issue relating to the ability of the chloride to act as a potential leaving group in the final compound.

The synthesis of novel 4- and 5-substituted-1,2,3-dithiazoles bearing a thiokeone, oxo, imino or ethyl 2-cyano-2-acetyl ylidene functionality at C-5 position were performed utilising the reaction between substituted ethanoneoximes and sulphur monochloride according to a one-pot protocol generating an in-situ pre-functionalised dithiazole salt intermediate before treatment with a selected nucleophile (Scheme 1).

![Scheme 1. Synthesis of dithiazole derivatives - Reagents and Conditions - (a) S2Cl2/Pyridine, CH2CN, Ar, -5 to 0 °C, 15 mins; (b) thioacetamide, 0 to 25 °C, CH2CN, Ar, 2 hr; (c) formic acid, CH2CN, Ar, 0 °C at 30 mins, 1 hr at reflux; (d) ethyl 2-cyanoacetate, pyridine, 25 °C, CH2Cl2, 5 hr; (e) aniline/benzyl amine, CH2CN, Ar, 0 °C at 30 mins, followed by pyridine.](image)

The ethanoneoximes 9a-g were prepared according to literature procedures in quantitative yields by heating a mixture of the corresponding ketones or aldehydes with an excess of hydroxylamine hydrochloride with sodium acetate in methanol at reflux. The oximes were subsequently suspended in acetonitrile and reacted with disulphur dichloride, with pyridine added dropwise to form the related dithiazolium salt intermediate, which was then treated with the appropriate nucleophilic source. A number of methods exist for the formation of 4-chloro-1,2,3-dithiazole-5-thione, including the use of hydrogen sulphide in acetonitrile or 2-cyanothioacetamide, but we chose to utilise thioacetamide for its ease of use and low cost. Thioacetamide was added after preparation of the dithiazole salt derivative and this selectively gave compounds 10a-e in good yields. 5-Oxodithiazoles were synthesised by replacing thioacetamide with formic acid, to produce 11a-c. 5-Minodithiazoles were prepared in a similar fashion by substituting thioacetamide with aniline to give 12a-d. Compound 13 was produced by treatment of the 9a dithiazolium salt derivative with ethyl cyanoacetate, although the modelling indicated that this compound was not optimal, we wanted to investigate if having a polar head group such as this cyano ester derivative would be tolerated.

Compounds 10-13 were then screened for toxicity in-vitro against feline kidney cells and tested for anti-viral efficacy in-vitro against a chronically infected feline lymphoid cell line.

concentrations; to determine the extent of viral replication/suppression. Viral RNA was isolated from cell culture supernatants using the MagNA Pure LC System by the Total Nucleic Acid Isolation Kit (Roche Applied Science). Viral loads were determined by quantitative real-time reverse transcription polymerase chain reaction (RT-qPCR).
remaining cells were subjected to a MTT cell viability assay to rule out any toxicity effects and validate that the RT-qPCR result is not
due to non-specific toxicity and provide a therapeutic index for each compound.

The results obtained demonstrated that activity was observed at varying potencies across each series with nanomolar activities as seen with 10a (Table 1). Toxicity was generally light when observed in the initial screening with CrFK cells with 24-hours exposure. This is generally a good indication of the level of toxicity that would be observed if there was a clearance mechanism in the FL-4 assay. There appears to be a roughly ten-fold increase in toxicity when looking at the results for the FL-4 assay relative to the CrFK data, but this has to be taken in the context of chronic exposure in an in-vitro assay and would not necessarily be truly representative of an in-vivo system. Importantly, the overall results show that even with prolonged exposure to these potentially zinc abstracting agents there is a good therapeutic index, which suggests that zinc abstraction is not intrinsically tied to cytotoxicity. The toxicity does not show any correlation with the activity displayed by the most active compounds such as 10a and 11b. While 12a also displays good activity and represents an improvement on previous work within our group, the therapeutic index (CC_{50}/EC_{50}) still requires further improvement.

After the initial promising result with 10a we looked to expand a small cluster of compounds around the main scaffold and alter structural features of the core compound to increase the

Table 1. Results from the 1,2,3-dithiazole scaffold FIV screening

[a] Sample concentration of 10 µM of compound on CrFK cells for 24 hours - percentage viability; [b] Geometric mean, each concentration tested in triplicate after 7 days as a difference of a untreated DMSO control FL-4 cells with a less than 10% error; [c] Therapeutic index is CC_{50}/EC_{50}, which is the ratio of toxicity to activity; [d] Calculated using ChemBioDraw Ultra 14.
therapeutic index. However, with 10b-e, we found there to be a drop off in activity when compared to 10a, with 10d and 10e showing unfavorable therapeutic indexes when compared to 10a, combined with lower overall activity. The slightly increased EC50 of 10c could be due to limited cell penetration compared to the other counterparts or the fact that sulphur is less electronegative relative to oxygen.55 This drop in activity was not observed with the switch to the oxygen analogue 11b which was almost as potent as 10a, but in displaying increased toxicity, the corresponding therapeutic index was lower. We expected a boost from a nitro group substitution (11c and 12c) but this modification led to an increase in toxicity with no material potency gain. The consistent substituent across each series was the para-methoxyphenyl group, which was used to screen the ‘head group’. Whilst the results of these compounds were quite consistent, they did not demonstrate improved potency but displayed increased toxicity when compared with 10a in this in-vitro system. Interestingly an increase in cLogP beyond 5 did not significantly inhibit the activity or affect the solubility of compounds 12a-c. 12d and 13 were investigated to understand if disruption to the core structure via removal of sulphur or oxygen would be tolerated and whilst activity was observed, there was not a significant improvement over 10a, due to an increased metabolic liability from the ethyl ester. The activity of azidothymidine (AZT) - 15 and raltegravir - 16 are consistent with previous reports in FIV/HIV.56,57

The focus of this work builds on the idea that the disulphide bridge is pivotal to the activity of the compounds against the NCp target, we also aimed to demonstrate that the disulphide is essential for activity by synthesizing a disrupted 1,2,3-dithiazole system with a disulphide bond by treatment of 10a with benzylamine (Scheme 2).56,59 to give 1,2,5-thiadiazolothione 14. However, we found the utility of this compound to be limited by toxicity, after prolonged cellular exposure. The EC50 closely mapped to the CC50 with a resulting therapeutic index of less than 2, this meant that this was not a definitive way to demonstrate if the disulphide bridge was essential or not. This observation may/may not support our hypothesis that the disulphide bridge was essential for the activity observed, but was not conclusive.

![Scheme 2. Reaction of 5H-1,2,3-dithiazole-5-thiones 10a to form 14 - Reagents and Conditions - (a) benzyl amine, THF, Ar, 3 hr, r.t.](image)

With the activities observed our proposed mechanism of action of this class of compound involves modification of the zinc-binding sites on the NCp of FIV which we determined using DFT calculations. Support for this idea comes from previous NMR and MS studies on HIV NCp7 that have shown observable formation of protein-zinc-thiol(ate) complexes and covalent modifcations.55 We reasoned that 1,2,3-dithiazole mediated zinc ion abstraction ejection also occurs via an analogous mechanism to known zinc binding/disrupting compounds in which a zinc-binding cysteinyl thiol(ate) reacts with the disulphide of the core to generate a transient protein-DTA disulphide (Figure 3).25,36,60 This can then rearrange to form an intramolecular protein disulphide with consequent reduction in zinc ion affinity. The ejected zinc ion (or zinc 1,2,3-dithiazole complex) could then potentially complex with a second (reduced) 1,2,3-dithiazole core to form a stable complex which is analogous to work previously reported on the epidithiodiketopiperazine class of natural products.60-62

![Figure 3. Proposed mechanism of action of 1,2,3-dithiazole for modification of NCp homology model. A - summary of the mechanism of zinc ejection from NCp/NCp7. B - a Zn2+ coordinating cysteine thiol(ate) reacts with the disulphide of the 1,2,3-dithiazole core to generate a transient intermediate disulphide. The disulphide then rearranges to form an intramolecular protein disulphide with consequent reduction in zinc ion affinity. The ejected zinc ion (or part Zn2+ complex) can then complex with a second 1,2,3-dithiazole core (reduced) to form a stable complex.](image)

Observations from our calculations show that it is unlikely that thermodynamic parameters drive the observed kinetics. Once disulphide exchange occurs between the zinc finger and the inhibitor, the zinc finger in the protein is no longer able to re-form and equilibrium to regenerate the structure is unable to be established. We therefore propose this mechanism using a kinetic argument whereby the energy barrier for zinc ejection is favored and in addition that the formation of a stable zinc complex is potentially thermodynamically favored. When the requisite disulphide bridge in the inhibitor is interrupted in compound 14, this disruption to the zinc finger can no longer occur and abstraction of zinc by our proposed mechanism is not available to this compound leading to the observed limited activity (Figure 4).
Figure 4. Global reactivity was estimated by calculation of the Fukui frontier molecular orbitals of 10-14 respectively and the propensity of the protein to undergo zinc abstraction. Fukui f+ negative visualized using iso-values 0.0015 (white) and 0.005 (green), (Schrödinger Maestro).

Conclusions

The sub-micromolar potencies of the compounds described in this study combined with the lower toxicities show a step change in progression towards the development of useful candidate compound for the targeting of the FIV/HIV nucleocapsid protein. The low toxicity and high activity of the initial hit 10a led us to believe that improved compounds with enhanced characteristics were possible. Many avenues of development exist such as a substitution at the para position of the pendant phenyl ring to prevent P450 metabolism while still maintaining activity. We demonstrated that 10a struck a good overall balance between activity and toxicity. With the quantum calculations demonstrating the viability of zinc ejection, this opens up the possibility of our investigations with the aim of generating lead structures with more favorable profiles. While we have enhanced the repertoire of the 5-thieno, 5-oxo, 5-imino-1,2,3-dithiazole class of compounds, the hope is that this work will allow us to generate a pre-clinical candidate that can treat both FIV and HIV in an in-vivo setting and this will be reported in due course.

Experimental Section

Modelling Calculations

Molecular Docking

A quantum polarized molecular docking study for a number of compounds (Figure 2) was conducted, which was similar to that previously generated using a homology model, with the version used in this study based on HIV-1 PDB:2JZW (NCp7) and EIAV PDB:2BL6 (NCp11) as a model for the FIV NCp. The inhibitory mechanism of compounds is assumed to begin with coordination of compounds against more the accessible zinc finger motif of the model (Figure 3). Our previous homology modelling and docking studies suggest that inhibitory activity can be partly explained by means of facile coordination of compounds close to the more accessible zinc finger structure.

DFT Molecular Orbital Calculations.

The zinc finger structure is not well described by means of molecular mechanics based molecular docking; hence we used Jaguar DFT calculations for docking pose derived model. The geometry of zinc finger cysteines and histidines were constrained to their initial geometry using Cartesian constraints to connector carbon atoms. B3LYP of theory and MSV basis set were used for geometry optimizations in the gas phase. Reactivity of selected compounds were separately estimated by unconstrained gas phase geometry optimizations (B3LYP/6-31g**) followed by single point Fukui frontier molecular orbital calculations (visualised in Figure 4). (Schrödinger Inc., New York, NY, USA).

Biological Studies

Initial Short Cytotoxicity Assay.

Crandell Reese feline kidney (CrFK) cells were cultured in 96-well plates (TPP, Trasadingen, Switzerland) at a density of 10,000 cells/well, in complete medium (RPMI 1640 medium (Sigma-Aldrich, Buchs, Switzerland), containing 10% Fetal Calf Serum (FCS) 100 M/mL Glutamine and 1% v/v antibiotic/antimycotic (Ab/Am) (all three, Gibco Life Technologies, Zug, Switzerland)). The antiviral compounds were dissolved in 2% DMSO (Sigma-Aldrich, Buchs, Switzerland) to make a 1M stock solution. The compounds were 10-fold serially diluted with complete medium.

Six dilutions of the compounds (100 µM to 1 nM) were added in triplicate on the CrFK cells (200 µL) and incubated for 24 hours (37 °C, 5% CO₂). The medium was removed and replaced with phenol red free medium and (180 µL) and methanol (200 µL) to reveal a bright purple formazan product. The methanol-formazan absorbance was determined at 570 nm (BioTek Synergy HT plate reader with KC4 software, Cambridge systems) values expressed as a 50% cytotoxic concentration (CC_{50}).

FIV Viral Loading Studies.

The potential antiviral effect against FIV was tested in a cell culture assay using an IL-2 independent feline FL-4 feline lymphoblastoid cell line. The compounds were added as concentrations ranges in triplicate as above. The cell supernatant (100 µL) was removed, frozen at -20 °C and replaced daily for 7 days. To determine the “long-term” cytotoxicity, on Day 7 the cell culture supernatant was replaced with phenol red free medium (80 µL) and the cells were subjected to the MTT assay (as before). The day 7 cell culture supernatants were centrifuged in a tabletop centrifuge (10000 x g) maximal speed for 2 min to pellet cells and debris. Cell culture supernatant of each triplicate were pooled and frozen immediately at -20 °C until analysis. Total nucleic acids (TNA) were extracted using the MagnaPure LC TNA extraction kit (Roche, Basel, Switzerland) from 100 µL of pooled according to manufacturer’s instructions. FIV RNA was quantitated by RT-
qPCR as described for FIV, using DMSO and untreated cells as controls. Results were expressed as 50% effective concentrations (EC50) determined by a sigmoid dose-response curve at 50% inhibition determined by sigmoid dose-response curve fitting using GraphPad Prism version 6.0 (GraphPad Inc., La Jolla, CA, USA) and an RNA standard.

Chemistry

General - Melting points were determined on a Kofler hot-stage apparatus and are uncorrected. IR spectra were recorded on a Specord M-80 instrument in KBr pellets. 1H NMR were recorded on a Bruker WM 300 spectrometer (300 MHz) and 13C NMR spectra were recorded on a Bruker AM 300 (75.5 MHz) in CDCl3. J values are given in hertz. Mass spectra were purified on a Finnigan MAT INCOS 50 instrument using electron impact ionization. Elemental analyses were performed on Perkin Elmer 2400 Elemental Analyser.

General Procedure A: 4-Phenyl-5H-1,2,3-dithiazole-5-thione (10a): Pyridine (0.243 ml, 3.0 mmol) was added dropwise at -5°C to a stirred solution of (E)-1-phenylethan-1-one oxime 9a(37) (135 mg, 1.0 mmol) and sulphur monochloride (0.160 ml, 2.0 mmol) in acetonitrile (10 ml) under an inert atmosphere of argon. The mixture was stirred at 0°C for 15 min. The reaction mixture was purified by column chromatography (Silica gel Merck 60, light petroleum and then light petroleum–CH2Cl2 mixtures) to afford compound 10a as a brown solid (155 mg, 73%). m.p. 95-100°C. Anal. Calcld. for C13H1N2S (%): C, 70.80; H, 5.74; N, 6.57; S, 17.09. Found (%): C, 70.72; H, 5.71; N, 6.60. IR (KBr), ν/cm-1: 3072 (υ(C≡N)), 1560 (υ(C═S)), 1364, 1276, 1140, 984, 824, 784.

4-Thienyl-5H-1,2,3-dithiazole-5-thione (10b): (E)-1-(Thiophen-2-yl)ethan-1-one oxime 9e(3) (141 mg, 1 mmol) was treated according to general procedure A to afford compound 10b as red crystals (94 mg, 25%). m.p. 89-92°C. Anal. Calcld. for C9H7NS (%): C, 73.16; H, 1.39; N, 6.44. Found (%): C, 73.28; H, 1.54; N, 6.14. IR (KBr), ν/cm-1: 3070 (υ(C≡N)), 1560 (υ(C═S)), 1364, 1276, 1140, 984, 824, 784.

4-Thienyl-5H-1,2,3-dithiazole-5-thione (10c): (E)-1-(Thiophen-3-yl)ethan-1-one oxime 9f(3) (141 mg, 1 mmol) was treated according to general procedure A to afford compound 10c as red crystals (94 mg, 25%). m.p. 89-92°C. Anal. Calcld. for C9H7NS (%): C, 73.16; H, 1.39; N, 6.44. Found (%): C, 73.28; H, 1.54; N, 6.14. IR (KBr), ν/cm-1: 3070 (υ(C≡N)), 1560 (υ(C═S)), 1364, 1276, 1140, 984, 824, 784.

4-(Fluorophenyl)-5H-1,2,3-dithiazole-5-thione (10d): (E)-1-(Fluorophenyl)ethan-1-one oxime 9g(3) (153 mg, 1 mmol) was treated according to general procedure A to afford compound 10d as yellow crystals (125 mg, 55%). m.p. 132-134°C. Anal. Calcld. for C13H1N2S (%): C, 74.79; H, 2.01; N, 5.97; S, 17.26. Found (%): C, 74.92; H, 2.03; N, 5.76. IR (KBr), ν/cm-1: 3072 (υ(C≡N)), 1560 (υ(C═S)), 1364, 1276, 1140, 984, 824, 784.

4-(Nitrophenyl)-5H-1,2,3-dithiazole-5-thione (10e): (E)-1-(Nitrophenyl)ethan-1-one oxime 9h(3) (153 mg, 1 mmol) was treated according to general procedure A to afford compound 10e as yellow crystals (84 mg, 35%). m.p. 155-156°C. Anal. Calcld. for C13H10N2O2S (%): C, 39.99; H, 1.68; N, 11.66. Found (%): C, 4.
**Ethyl (2)-cyano-2-(4-(4-fluorophenyl))-5H1,2,3-dithiazol-5-yldiene)acetate (13):** Sulphur monochloride (0.32 mL, 4 mmol) and pyridine (0.48 mL, 6 mmol) were successively added dropwise to a solution of (E)-1-(4-(4-fluorophenyl))ethan-1-one oxime (9c) (153 mg, 1 mmol) in dichloromethane (15 mL) at −7 °C under argon. The reaction mixture was kept at −2 °C for 20 min and a solution of ethyl 2-cynoacetate (1.13 g, 10 mmol) in acetonitrile (10 mL) was added dropwise at −15 °C and the resulting mixture was stirred for 1 h. Pyridine (0.32 mL, 4 mmol) was added dropwise at −15 °C, the temperature was raised to room temperature and solvent evaporated under reduced pressure. The residue was purified by column chromatography (Silica gel Merck 60, light petroleum and then light petroleum:CH₂Cl₂ mixtures) to afford compound 13 as orange crystals (49 mg, 16%): m.p. 188-193 °C. Anal. Calcd for C₂₃H₁₈F₂N₂O₂: C, 70.49; H, 4.12; N, 10.12. 1H NMR (300 MHz, CDCl₃): δ: 1.38 (3H, t, J = 7.3 Hz, CH₃), 4.37 (2H, q, J = 7.3 Hz, CH₂), 7.21 (2H, t, J = 8.5 Hz, Ar), 7.46 (2H, m, Ar). 13C NMR (75.5 MHz, CDCl₃): δ: 14.3 (CH₃), 63.2 (CH₂), 116.1 (2 CH₂), 131.5 (2 CH), 90.3, 113.1, 126.8, 163.3, 163.1, 166.3, 167.5 (7 sp² C). MS (EI, 70 eV), m/z (%): 308 (M⁺, 62), 235 (100), 153 (22). IR (KBr), ν/cm⁻¹: 2928 (C-H), 2204 (CN), 1664, 1520, 1444, 1280, 1104, 824, 792, 700.

**Ethyl (2)-phenyl-1,2,5-thiadiazole-3(2H)-thione (14):** Benzyl amine (0.109 mL, 1 mmol) was added to a solution of 4-Phenyl-1H-1,2,3-dithiazole-5-thione (10a) (0.106 mg, 0.5 mmol) in THF (4 mL) at room temperature. The reaction mixture was stirred for 3 h at room temperature, the alkylammonium hydrogen sulphide was filtered off, and the solvent evaporated under reduced pressure. The residue was purified by column chromatography (Silica gel Merck 60, light petroleum:CH₂Cl₂ mixtures) to afford compound 14 as a yellow crystalline solid (80 mg, 56%): m.p. 95-97 °C; Anal. Calcd for C₂₃H₁₈N₂S²: C, 63.35; H, 4.25; N, 9.85; S, 22.55. Found (%): C, 63.45; H, 4.39; N, 10.05; S, 22.68. 1H NMR (300 MHz, CDCl₃): δ: 5.31 (2H, s, CH₂), 7.49 (8H, m, Ar), 8.42 (2H, m, Ar). 13C NMR (75.5 MHz, CDCl₃): δ: 53.8 (CH₂), 128.1 (2 CH₂, Ar), 129.9 (2 CH, Ar). MS (EI, 70 eV), m/z (%): 306.4 (M⁺, 25), 2928 (C-H), 2852, 1496, 1456, 1428, 1344, 1332, 1292, 1208, 1028, 848, 772, 756, 708, 696.

Evaluation of substituted dithiazole derivatives as inhibitors of the Feline Immunodeficiency Virus (FIV) via a proposed zinc ejection mechanism

A diverse library of 1,2,3-dithiazole derivatives have been synthesized and tested against Feline Immunodeficiency Virus (FIV) in cells using Density Functional Theory (DFT) to determine a degree of suitability in a simplified nucleocapsid homology model. The compounds displayed nanomolar activity and relatively low toxicity and represent a new class of compounds for the treatment of FIV and HIV. This work demonstrates the versatility of the 1,2,3-dithiazole scaffold, adding anti-viral abilities to the portfolio of biological activities already known for this class of compound.
