

Singular Limit of Navier-Stokes System Leading to a Free/Congested Zones Two-Phase model

Didier Bresch, Charlotte Perrin and Ewelina Zatorska

Abstract. The aim of this work is to justify mathematically the derivation of a viscous free/congested zones two-phase model from the isentropic compressible Navier-Stokes equations with a singular pressure playing the role of a barrier.

Titre et résumé en Français. *Modèle bi-phasique gérant zones libres/zones congestionnées comme limite singulière d'un système de Navier-Stokes compressible.* Le but de ce papier est de justifier mathématiquement l'obtention d'un modèle biphasique visqueux gérant zones libres/zones congestionnées comme limite singulière des équations de Navier-Stokes compressible barotrope à l'aide d'une pression singulière jouant le rôle d'une barrière. Ce type de systèmes macroscopiques pour modéliser le mouvement de foule a été proposé dans de nombreux papiers. Le lecteur intéressé est renvoyé par exemple au papier de review [B. MAURY, Actes des Colloques Caen 2012-Rouen 2011].

Mathematics Subject Classification (2010). Primary 35Q35; Secondary 74N20.

Keywords. Singular pressure, compressible Navier-Stokes equations, free/congested, two-phase flows.

1. Introduction

Macroscopic approaches for modelling the motion of crowd have been recently proposed in various papers where the swarm is identified through a density $\rho = \rho(t, x)$, see for instance a review paper by MAURY [12]. The density is transported through a vector field $u(t, x)$ which itself solves an equation

This work was completed with the support of our \TeX -pert.

expressing the variation of velocity for each individual under some factors. The following system is obtained

$$\begin{cases} \partial_t \rho + \operatorname{div}(\rho u) = 0, \\ \partial_t(\rho u) + \operatorname{div}(\rho u \otimes u) = F(\rho, u), \end{cases} \quad (1.1)$$

where F is an appropriate differential operator that has to be defined depending on the applications; for instance, repulsive/attractive terms may be included to model congestion.

For modelling the traffic jams, some systems that mix free/congested regions have been also proposed, namely

$$\begin{cases} \partial_t \rho + \operatorname{div}(\rho u) = 0 \\ \partial_t(\rho u) + \operatorname{div}(\rho u \otimes u) + \nabla \pi = 0 \\ 0 \leq \rho \leq \rho^*, \quad (\rho - \rho^*)\pi = 0 \end{cases} \quad (1.2)$$

for given function ρ^* . The interested reader is referred to paper by BERTHELIN [1] in which the existence of solutions to system (1.2) was proven for $\rho^* = \text{const.}$ using the convergence of some special solutions, called the sticky blocks. For various extensions of this work (when ρ^* depends on the velocity or on the number of lanes in the portion of the road) we refer to a recent work of BERTHELIN and BROIZAT [2] and the references therein.

Formal justification of system (1.2) from (1.1) with $F(\rho, u)$ being a gradient of a specific singular pressure term has been given by DEGOND *et al.* in [7] (see also the proposed numerical scheme for $\rho^* = 1$). Note that a more complex model than (1.2) has been also formally derived by these authors for collective motion (namely with the extra constraint on the velocity $|u| = 1$).

The main objective of this note is to justify mathematically the viscous version of (1.2) as a limit of the isentropic compressible Navier-Stokes equations. This limit will be obtained by introducing a small parameter ε in front of a singular pressure and by letting $\varepsilon \rightarrow 0$. The important feature of such system is that it preserves the constraint $0 \leq \rho^\varepsilon \leq 1$ for any $\varepsilon > 0$ fixed.

2. Singular compressible Navier-Stokes model and the associated free boundary system

We consider the system of compressible barotropic Navier-Stokes equations

$$\begin{cases} \partial_t \rho^\varepsilon + \operatorname{div}(\rho^\varepsilon u^\varepsilon) = 0 \\ \partial_t(\rho^\varepsilon u^\varepsilon) + \operatorname{div}(\rho^\varepsilon u^\varepsilon \otimes u^\varepsilon) - 2\operatorname{div}(\mu(\rho^\varepsilon)D(u^\varepsilon)) \\ - \nabla(\lambda(\rho^\varepsilon)\operatorname{div}(u^\varepsilon)) + \nabla p_1(\rho^\varepsilon) + \nabla p_2^\varepsilon(\rho^\varepsilon) = 0 \end{cases} \quad (2.1)$$

in a fixed bounded domain Ω .

In the above system p_1 is the barotropic pressure

$$p_1(\rho^\varepsilon) = a(\rho^\varepsilon)^\alpha \quad a \geq 0, \quad \alpha > 1, \quad (2.2)$$

while p_2^ε is the singular pressure in the spirit of [5, 8]

$$p_2^\varepsilon(\rho^\varepsilon) = \varepsilon(\rho^\varepsilon)^\gamma P(\rho^\varepsilon), \quad \gamma > 1, \quad \varepsilon > 0. \quad (2.3)$$

The singular pressure $P(\cdot) \in \mathcal{C}^1(0, 1)$ is strictly increasing function, such that

$$\lim_{\rho^\varepsilon \rightarrow \rho_*^-} P(\rho^\varepsilon) = +\infty \quad (2.4)$$

and $\rho_* = 1$ stands for the upper threshold of the density.

We supplement system (2.1) with the following initial conditions

$$\rho^\varepsilon(x)|_{t=0} = \rho_0^\varepsilon(x), \quad u^\varepsilon(0)|_{t=0} = u_0^\varepsilon(x) \quad x \in \Omega, \quad (2.5)$$

where

$$0 \leq \rho_0^\varepsilon \leq 1, \quad \int_{\Omega} \rho_0^\varepsilon = M \quad (2.6)$$

and the Dirichlet boundary conditions

$$u^\varepsilon|_{\partial\Omega} = 0.$$

Our concern is to investigate the limit when ε tends to zero and justify that $(\rho^\varepsilon, u^\varepsilon, p_2^\varepsilon(\rho^\varepsilon))$ tends (in some sense) to (ρ, u, π) which satisfies the following free boundary problem

$$\begin{cases} \partial_t \rho + \operatorname{div}(\rho u) = 0 \\ \partial_t(\rho u) + \operatorname{div}(\rho u \otimes u) \\ \quad - 2\operatorname{div}(\mu(\rho)D(u)) - \nabla(\lambda(\rho)\operatorname{div}(u)) + \nabla p_1(\rho) + \nabla \pi = 0 \end{cases} \quad (2.7)$$

with

$$\begin{cases} 0 \leq \rho \leq 1, \\ \pi \geq 0, \\ (1 - \rho)\pi = 0. \end{cases} \quad (2.8)$$

Such free boundary system has been derived by LIONS and MASMOUDI [11] where they considered $p_\gamma(\rho) = a\rho^\gamma$ with γ tending to $+\infty$. The same limit has been studied in [9] with viscosities depending on the density when some surface tension is included. However, such form of pressure does not guarantee the congestion constraint $0 \leq \rho^\gamma \leq 1$ for fixed γ , which is a problem for numerical investigation, as mentioned in the recent paper by MAURY [12]. We will see that the pressure P defined in (2.4) plays a role of a barrier and implies that the constraint $0 \leq \rho^\varepsilon \leq 1$ is automatically satisfied for any $\varepsilon > 0$. This, however, asks for a special behavior of $P(\cdot)$ close to 1. An important example of such barrier used for instance in Self-Organized Hydrodynamics [6], [7] is of the form

$$p^\varepsilon(\rho^\varepsilon) = \varepsilon \left(\frac{1}{\frac{1}{\rho^\varepsilon} - 1} \right)^\gamma = \varepsilon \left(\frac{\rho^\varepsilon}{1 - \rho^\varepsilon} \right)^\gamma.$$

3. One-dimensional case

The aim of this section is to prove the global-in-time existence of regular solutions to system (2.1) when $\Omega = [0, L]$ and μ, λ are positive constants. We will also perform the limit passage leading to the free boundary system (2.7–2.8). More precisely, we prove the following results

Theorem 3.1. *Let $\varepsilon, \mu, \lambda$ be fixed positive constants and let $(u^0, \rho^0) \in H_0^1(0, L) \times H^1(0, L)$ with $0 < \rho^0 < 1$. Assume that the singular pressure satisfies*

$$P(\rho) = (1 - \rho)^{-\beta} \quad (3.1)$$

with $\beta, \gamma > 1$. Then there exists a regular solution $(u^\varepsilon, \rho^\varepsilon)$ to (2.1–2.4) such that

$$\begin{aligned} \|\rho^\varepsilon\|_{L^\infty(0, T; H^1(0, L))} + \|\rho^\varepsilon\|_{H^1(0, T; L^2(0, L))} &\leq c, \\ \|u^\varepsilon\|_{L^2(0, T; H_0^1(0, L))} + \|u^\varepsilon\|_{L^\infty(0, T; L^2(0, L))} &\leq c \end{aligned}$$

uniformly with respect to ε and there exist constants c and $C(\varepsilon)$ s.t.

$$0 < c \leq \rho^\varepsilon \leq C(\varepsilon) < 1. \quad (3.2)$$

Remark 3.2. The full regularity and uniqueness of this solution for ε fixed can also be proved, see Theorem 3.4 below. However the proof relies on the estimates which strongly depend on ε .

Theorem 3.3. *Under assumptions of the previous theorem, there exists a subsequence already denoted $(\rho^\varepsilon, u^\varepsilon, \pi^\varepsilon)$ s.t.*

$$\begin{aligned} \rho^\varepsilon &\rightarrow \rho && \text{in } \mathcal{C}([0, T] \times [0, L]), \\ u^\varepsilon &\rightarrow u && \text{in } L^2(0, T; \mathcal{C}[0, L]), \\ \pi^\varepsilon &= p_2^\varepsilon \rightharpoonup \pi && \text{in } \mathcal{M}^+((0, T) \times (0, L)), \end{aligned} \quad (3.3)$$

where (u, ρ, π) satisfies (2.7–2.8).

3.1. Proof of Theorem 3.1

As mentioned before, Theorem 3.1 may be obtained as a corollary of a stronger result formulated below in Theorem 3.4 by use of Lagrangian coordinates.

We drop the index ε when no confusion can arise and we define

$$x = \int_0^x \rho(\tau, s) ds, \quad \tau = t. \quad (3.4)$$

Using (3.4) and denoting $\nu = 2\mu + \lambda$, system (2.1) may be transformed into the following one

$$\begin{cases} \rho_\tau + \rho^2 u_x = 0 \\ u_\tau - \nu(\rho u_x)_x + (p_1(\rho))_x + (p_2^\varepsilon(\rho))_x = 0 \end{cases} \quad (3.5)$$

with the Dirichlet boundary conditions

$$u|_{x=0} = u|_{x=M} = 0$$

and the initial data

$$\rho|_{\tau=0} = \rho_0, \quad u|_{\tau=0} = u_0, \quad \text{in } [0, M], \quad (3.6)$$

such that

$$0 < \rho_0 < 1. \quad (3.7)$$

For the above system we will prove the following theorem.

Theorem 3.4. *Assume that $(u^0, \rho^0) \in H_0^1(0, M) \times H^1(0, M)$ and that (3.7) is satisfied. Then system (3.5-3.6) possesses a global unique solution (ρ, u) such that*

$$\begin{aligned} \rho &\in L^\infty(0, T; H^1(0, M)), \quad \rho_\tau \in L^2((0, T) \times (0, M)), \\ u_x &\in L^\infty(0, T; L^2(0, M)) \cap L^2(0, T; H^1(0, M)). \end{aligned} \quad (3.8)$$

Moreover there exist positive constants c_ρ, C_ρ such that

$$0 < c_\rho \leq \rho^\varepsilon \leq C_\rho(\varepsilon) < 1. \quad (3.9)$$

The local in time solvability of system (2.1-2.6) with monotone pressure, is a classical result, see f.i. [14]. Therefore, in order to show global in time existence it is enough to prove uniform in time estimates. This will be a purpose of the following paragraphs.

To deduce bounds on the density we first test (3.5)₂ by u and then by $\frac{\rho_x}{\rho}$ and we sum the obtained expressions. This leads to

$$\sup_{\tau \in (0, T)} \int_0^M ((\log \rho)_x)^2(\tau) dx + \int_0^T \int_0^M \left| (p_2^\varepsilon)'(\rho) \frac{(\rho_x)^2}{\rho} \right| dx d\tau \leq c. \quad (3.10)$$

The lower bound is deduced from the control of the first integral while boundedness of the second integral clearly forces the upper bound, recall that $\beta > 1$.

It is then natural to expect that u is more regular than it follows from the basic energy estimate. Regularity (3.8) can be shown in a standard way, by testing (3.5)₂ by $-u_{xx}$. The proof of uniqueness is then straightforward. \square

Note that (3.8) allows to back to Eulerian coordinates, since $\partial_t h(t, x) = \partial_\tau h(\tau, x) - u(\tau, x)\rho(\tau, x)\partial_x h(\tau, x)$ and $\partial_x h(t, x) = \rho(\tau, x)\partial_x h(\tau, x)$ which finishes the proof of Theorem 3.1. \square

3.2. Recovering the two-phase system

In this subsection we prove Theorem 3.3. Let us first focus on establishing the estimates which are uniform with respect to ε . The basic energy equality for system (2.1) in the Eulerian coordinates reads

$$\frac{d}{dt} \int_0^L \left(\frac{1}{2} \rho^\varepsilon |u^\varepsilon|^2 + \rho^\varepsilon (e_1(\rho^\varepsilon) + e_2^\varepsilon(\rho^\varepsilon)) \right) + \nu \int_0^L |\partial_x u^\varepsilon|^2 = 0 \quad (3.11)$$

with $e_1(\rho^\varepsilon) = \frac{a}{\alpha-1}(\rho^\varepsilon)^{\alpha-1}$ and $e_2^\varepsilon(\rho^\varepsilon) = \int_0^{\rho^\varepsilon} \frac{p_2^\varepsilon(s)}{s^2} ds$. As in [11], the bound on $\rho e_2^\varepsilon(\rho^\varepsilon)$ does not provide bound for p_2^ε uniform with respect to ε . To solve this problem we perform a Bogovskii-type of estimate. Note that the arguments to conclude will be different than in [11].

Uniform estimate of the pressure. We test the momentum equation in (2.1) by $\phi(t, x) = \psi(t) \left(\int_0^x \rho^\varepsilon(t, y) dy - \bar{\rho}^\varepsilon \right)$, where $\bar{\rho}^\varepsilon = \frac{1}{L} \int_0^L \rho^\varepsilon(x, t) dx$ and $\psi(t) \in \mathcal{C}_0^\infty((0, L))$, we obtain

$$\begin{aligned} \int_0^T \psi \int_0^L (p_1 + p_2^\varepsilon) (\rho^\varepsilon - \bar{\rho}^\varepsilon) dx dt &= - \int_0^T \psi' \int_0^L \rho^\varepsilon u^\varepsilon \left(\int_0^x \rho^\varepsilon dy - \bar{\rho}^\varepsilon \right) dx dt \\ &\quad + \int_0^T \psi \bar{\rho}^\varepsilon \int_0^L \rho^\varepsilon (u^\varepsilon)^2 dx dt + \nu \int_0^T \psi \int_0^L u_x (\rho^\varepsilon - \bar{\rho}^\varepsilon) dx dt \end{aligned}$$

The r.h.s. is controlled thanks to (3.11) and (3.9), thus the l.h.s. is bounded uniformly with respect to ε . We then split the l.h.s. into two terms

$$I_1 + I_2 = \int_{\{\rho^\varepsilon < \frac{\bar{\rho}_0 + 1}{2}\}} p_2^\varepsilon (\rho^\varepsilon - \bar{\rho}^\varepsilon) dx dt + \int_{\{\rho^\varepsilon \geq \frac{\bar{\rho}_0 + 1}{2}\}} p_2^\varepsilon (\rho^\varepsilon - \bar{\rho}^\varepsilon) dx dt \leq c.$$

The integrant in I_1 is far away from singularity, thus it is bounded, whence the integrant in I_2 is larger than $\frac{1-\bar{\rho}_0}{2} p_2^\varepsilon$ which implies that $p_2^\varepsilon = \varepsilon p_2(\rho^\varepsilon)$ is bounded in $L^1((0, T) \times (0, L))$ uniformly with respect to ε . The same conclusion can be drawn for $p_2^\varepsilon \rho^\varepsilon$.

Passage to the limit $\varepsilon \rightarrow 0$. Using the Arzelà-Ascoli theorem we prove that

$$\rho^\varepsilon \rightarrow \rho \quad \text{in } \mathcal{C}([0, T] \times [0, L]), \quad (3.12)$$

and (3.9) implies that $p_1(\rho^\varepsilon) \rightarrow p_1(\rho)$ strongly in $\mathcal{C}([0, T] \times [0, L])$.

Thanks to the uniform bounds on the pressure, up to a subsequence, we have

$$p_2^\varepsilon(\rho^\varepsilon) \rightharpoonup \pi, \quad \rho^\varepsilon p_2^\varepsilon(\rho^\varepsilon) \rightharpoonup \pi_1 \quad \text{in } \mathcal{M}^+((0, T) \times (0, L)), \quad (3.13)$$

but thanks to (3.12) we may identify the second limit as

$$\rho^\varepsilon p_2^\varepsilon(\rho^\varepsilon) \rightharpoonup \rho \pi \quad \text{in } \mathcal{M}^+((0, T) \times (0, L)). \quad (3.14)$$

Concerning the convergence of the velocity, by (3.11) we deduce that

$$u^\varepsilon \rightharpoonup u \quad \text{in } L^2(0, T; H_0^1(0, L)), \quad u^\varepsilon \rightharpoonup^* u \quad \text{in } L^\infty(0, T; L^2(0, L))$$

up to a subsequence. Therefore $\rho^\varepsilon u^\varepsilon \rightharpoonup \rho u$ in $L^4((0, T) \times (0, L))$. In addition, $(\rho^\varepsilon u^\varepsilon)_x$ is uniformly bounded in $L^2((0, T) \times (0, L))$. From the momentum equation and the L^1 bound on the pressure we can assert that $(\rho^\varepsilon u^\varepsilon)_t \in L^1(0, T; W^{-1,1}(0, L))$. Thus, an application of the generalized Aubin-Lions lemma [13]) yields

$$\rho^\varepsilon u^\varepsilon \rightarrow \rho u \quad \text{in } L^2(0, T; \mathcal{C}[0, L]).$$

Hence, (3.9) and (3.12) imply strong convergence of u^ε , as stated in (3.3).

In order to conclude it remains to prove that (ρ, π) satisfies constraint (2.8)₃. Due to singularity of the pressure, we cannot use the same argument as in [11]. Nevertheless, using (3.1) we may write

$$\varepsilon \rho^\varepsilon p_2^\varepsilon(\rho^\varepsilon) = -\varepsilon \frac{(\rho^\varepsilon)^\gamma}{(1 - \rho^\varepsilon)^{\beta-1}} + \varepsilon p_2^\varepsilon(\rho^\varepsilon). \quad (3.15)$$

Letting $\varepsilon \rightarrow 0$, we see that the l.h.s. converges to $\rho \pi$ and the second term on the r.h.s. converges to π , on account of (3.14) and (3.13) respectively, while the middle term vanishes due to the uniform bound on p_2^ε . \square

4. Multi-dimensional case

Let us now comment what are main differences in the proof for the multi-dimensional case, we refer to [?] for more details.

- In general, the global-in-time regular solutions are not known to exist, thus one needs to work with the weak solutions.
- The constraint $0 \leq \rho^\varepsilon \leq 1$ can be obtained for sufficiently strong singularity in the pressure (i.e. $\beta > 3$), otherwise it holds only for the limit.
- The strong convergence of density is not an automatic consequence of the a-priori estimates. For this reason, verification of (3.14) requires some compactness of the so-called *effective pressure*.

Acknowledgment

The first author wants to thank B. MAURY for some discussions regarding the use of barrier singular pressure for congestion problems. He also acknowledges support from the ANR-13-BS01-0003-01 DYFICOLTI.

The third author thanks E. FEIREISL and A. NOVOTNÝ for their helpful remarks on the limit system. She was supported by the Polish National Science Center Grant DEC-2011/01/N/ST1/01776.
