# Almost partitioning the hypercube into copies of a graph 

Vytautas Gruslys* Shoham Letzter ${ }^{\dagger}$

September 19, 2018

#### Abstract

Let $H$ be an induced subgraph of the hypercube $Q_{k}$, for some $k$. We show that for some $c=c(H)$, the vertices of $Q_{n}$ can be partitioned into induced copies of $H$ and a remainder of at most $O\left(n^{c}\right)$ vertices. We also show that the error term cannot be replaced by anything smaller than $\log n$.

## 1 introduction

Given graphs $G$ and $H$, an $H$-packing of $G$ is a collection of vertex-disjoint copies of $H$ in $G$. A perfect $H$-packing (also known as an $H$-factor) is an $H$-packing that covers all the vertices of the ground graph $G$ (so, in order for $G$ to have a perfect $H$-packing, $|H|$ must divide $|G|$ ). A natural question asks for conditions on $G$ that imply the existence of an $H$-factor. For example, a well researched question asks for the smallest minimum degree that implies the existence of an $H$-factor. If $H$ is an edge (and more generally if $H$ is a path), then, by Dirac's theorem [4], if $G$ has $n$ vertices and minimum degree at least $n / 2$ (and $|H|$ divides $|G|$ ), then $G$ has a perfect $H$-packing. Corrádi and Hajnal [3] showed that $\delta(G) \geq 2 n / 3$ guarantees the existence of a perfect $K_{3}$-packing and Hajnal and Szemerédi [8] extended this result by showing that if $\delta(G) \geq(1-1 / r) n$ then $G$ has a perfect $K_{r}$-packing. We remark that these conditions on $\delta(G)$ are best possible.

After a series of papers by Alon and Yuster [1, 2] and by Komlós, Sárközy and Szemerédi [9], Kuhn and Osthus [10] found the smallest minimum degree condition that guarantees the existence of an $H$-factor, up to an additive constant error term, and for all $H$.

We consider a different problem, where instead of looking for $H$-packings in graphs of large minimum degree, we focus on $H$-packings of the hypercube $Q_{n}$. There are two obvious conditions for the

[^0]existence of a perfect $H$-packing in $Q_{n}$ : $H$ has to be a subgraph of $Q_{n}$; and the order of $H$ has to be a power of 2 . Gruslys [5] showed that these two conditions are sufficient for large $n$, thus confirming a conjecture of Offner [12]. In fact, he showed that if $H$ is an induced subgraph of $Q_{k}$ for some $k$ and $|H|$ is a power of 2 , then there is a perfect packing of $G$ into induced copies of $H$.

A similar problem concerns packings of the Boolean lattice $2^{[n]}$ into induced copies of a poset $P$. Note that here, if we drop the induced condition, we reduce to the case where $P$ is a chain, thus in the case of posets we only consider induced copies of $P$. Again, there are two obvious necessary conditions: $P$ must have a minimum and maximum elements; and the order of $P$ has to be a power of 2 . Lonc [11] conjectured that for large enough $n$, these conditions are also sufficient, and verified the conjecture for the case where $P$ is a chain. This conjecture was recently solved by Gruslys, Leader and Tomon [7].

It is natural to ask what can be said when the divisibility condition does not hold. Gruslys, Leader and Tomon [7] conjectured that if $P$ is a poset with a maximum and a minimum, then there is a $P$-packing of $Q_{n}$ that covers all but at most $c$ elements, where $c=c(P)$ is a constant that depends on $P$. This conjecture was recently proved by Tomon [14].

In light of this result, it is natural to ask if a similar phenomenon holds in the case of $H$-packings of the hypercube $Q_{n}$. Namely, if $H$ is a subgraph of $Q_{k}$ for some $k$, how large an $H$-packing of $Q_{n}$ can we find? As our first main result, we show that if $H$ is a subgraph of $Q_{k}$ then there is an $H$-packing of $Q_{n}$ that covers all but at most $O\left(n^{c}\right)$ vertices, where $c=c(H)$.

Theorem 1. Let $H$ be an induced subgraph of $Q_{k}$ for some $k$. Then there exists a packing of $G$ by induced copies of $H$, such that at most $O\left(n^{c}\right)$ vertices remain uncovered, where $c=c(H)$.

It is natural to wonder if the number of uncovered vertices can be reduced to be at most $c(H)$. Perhaps surprisingly, it turns out that this is not always the case. As our second main result, we show that a $\left(P_{3}\right)^{3}$-packing of $Q_{n}$ misses at least $\log n$ vertices ( $P_{3}$ is the path on three vertices).

Theorem 2. In every $\left(P_{3}\right)^{3}$-packing of $Q_{n}$, at least $\log n$ points are uncovered.

### 1.1 Notation

We denote the path on $l$ vertices by $P_{l}$. When we say that $G$ can be partitioned into copies of $H$, we mean that there exists a perfect $H$-packing of $G$. For graphs $G_{1}$ and $G_{2}$, we denote by $G_{1} \times G_{2}$ the Cartesian product of $G_{1}$ and $G_{2}$, which has vertex set $V\left(G_{1}\right) \times V\left(G_{2}\right)$ and $\left(\left(u_{1}, v_{1}\right),\left(u_{2}, v_{2}\right)\right)$ is an edge iff $u_{1}=v_{1}$ and $u_{2} v_{2} \in E\left(G_{2}\right)$ or $u_{2}=v_{2}$ and $u_{1} v_{1} \in E\left(G_{1}\right)$. The $n$-th power $G^{n}$ of $G$ is defined to be $G \times \ldots \times G$ (where $G$ appears $n$ times).

### 1.2 Structure of the paper

This paper consists of three parts. In the first part (see Section 3) we prove that if $H$ is an induced subgraph of $Q_{k}$ for some $k$, then for sufficiently large $n$, there is a perfect packing of $\left(P_{2|H|}\right)^{n}$ into induced copies of $H$ (see Theorem 3). In the second part (Section 4), we prove that there is a packing of $Q_{n}$ by induced copies of $\left(P_{l}\right)^{t}$ which leaves at most $O\left(n^{t-1}\right)$ vertices uncovered. These two parts easily combine to form a proof of Theorem 1. Finally, in the third part (Section 5) we prove Theorem 2, thus showing that the error term $O\left(n^{t-1}\right)$ cannot be replaced by something smaller than $\log n$.

Before proceeding to the proofs, we give an overview of them in Section 2. We finish the paper with concluding remarks and open problems in Section 6.

## 2 Overview of the proofs

In this section we give an overview of the proofs in this paper.

### 2.1 Partitioning $\left(P_{2 l}\right)^{n}$

Our first aim in this paper is to prove Theorem 3.
Theorem 3. Let $H$ be an induced subgraph of $Q_{k}$ for some $k$. Then $\left(P_{2|H|}\right)^{n}$ can be partitioned into induced copies of $H$, whenever $n$ is sufficiently large.

Our proof follows the footsteps of Gruslys [5] who proved that if $H$ is an induced subgraph of a hypercube whose order is a power of 2 , then for large $n$ there is a perfect packing of $Q_{n}$ into induced copies of $H$.

An important tool in the proof of Theorem 3 is a result of Gruslys, Leader and Tomon [7] (introduced by Gruslys, Leader and Tan [6] for tiling of $\mathbb{Z}^{n}$ ) which gives a a general method for proving the existence of perfect packings of a product space $A^{n}$ into copies of a subset $S$ of $A$. Given a subset $S$ of $A$, a collection of copies of $S$ in $A^{n}$ (which may contain a certain copy several times) is called an $l$-partition $\left((r \bmod l)\right.$-partition) if every vertex in $A^{n}$ is covered by exactly $l((r \bmod l))$ copies of $S$. We note that a 1-partition is simply a perfect packing. Trivially, the existence of a perfect packing implies the existence of an $l$-partition and a $(1 \bmod l)$-partition. Remarkably, the aforementioned result of Gruslys, Leader and Tomon shows that, roughly speaking, the opposite is true. Namely, they showed that if there exists $l$ for which $A^{m}$ admits an $l$-partition and a $(1 \bmod l)$-partition into copies of $S$, then, for large $n, A_{n}$ admits a perfect packing into copies of $S$. The precise statement of this result is given in Theorem 5.

The existence of an $|H|$-partition of $\left(P_{2|H|}\right)^{n}$ into induced copies of $H$ is a simple observation (see Observation 6). The existence of a $(1 \bmod |H|)$-partition of $\left(P_{2|H|}\right)^{n}$ into copies of $H$ is more difficult to prove, but it is quite straightforward to adapt the methods of Gruslys [5] to work in our setting. These two facts, together the aforementioned result [7], form the proof of Theorem 3.

### 2.2 Almost partitioning $Q_{n}$ into powers of a path

Our second aim is to prove Theorem 4.
Theorem 4. For any $l$ and $t$, there is a packing of $Q_{n}$ into induced copies of $\left(P_{l}\right)^{t}$, for which at most $O\left(n^{t-1}\right)$ vertices are uncovered.

The fact that $Q_{n}$ is Hamiltonian shows that there is a $P_{l}$-packing of $Q_{n}$ missing fewer than $l$ vertices. In fact, if $l$ divides $2^{n}-1$, then exactly one vertex remains uncovered. This observation allows us to prove the existence of a $\left(P_{l}\right)^{t}$-packing of $Q_{n}$ with at most $O\left(n^{t-1}\right)$ uncovered vertices, whenever $l$ is odd (see Observation 8). It is then not hard to conclude that the same holds for all $l$ (see Corollary 9) using the observation that $\left(P_{2 l}\right)^{t}$ is a subgraph of $\left(P_{l}\right)^{t} \times Q_{t}$.

Note that this does not imply Theorem 4, since we require that the copies of $\left(P_{l}\right)^{t}$ are induced. We notice that if $H$ is a graph on $l$ vertices with a Hamilton path, then $H \times P_{l-1}$ has a perfect packing into induced $P_{l}$ 's (see Observation 11). This fact, with a little more work, allows us to use the packing of $Q_{n}$ into (not necessarily induced) copies of $\left(P_{l^{\prime}}\right)^{t}$ to obtain a packing into induced copies of $\left(P_{l}\right)^{t}$ (where $l^{\prime}$ is suitably chosen).

We note that Theorem 1 follows from Theorems 3 and 4.

Proof of Theorem 1. Let $H$ be a subgraph of $Q_{k}$. Then by Theorem 3, there exists $m$ for which there is a perfect packing of $\left(P_{2|H|}\right)^{m}$ into induced copies of $H$. By Theorem 4, there is a packing of $Q_{n}$ into induced copies of $\left(P_{2|H|}\right)^{m}$, such that at most $O\left(n^{m-1}\right)$ vertices are uncovered. Hence there exists a packing of $Q_{n}$ into induced copies of $H$ with at most $O\left(n^{m-1}\right)$ uncovered vertices (note that $m$ depends only on $H$ ).

### 2.3 Lower bound on the number of uncovered vertices

Our final aim is to prove Theorem 2.
Theorem 2. In every $\left(P_{3}\right)^{3}$-packing of $Q_{n}$, at least $\log n$ points are uncovered.
We use the properties of $Q_{n}$ and of $\left(P_{3}\right)^{3}$ to conclude that the size of the intersection of any co-dimension-2 subcube of $Q_{n}$ with any copy of $\left(P_{3}\right)^{3}$ is divisible by 3 . In fact, we deduce this from a similar statement for $\left(P_{3}\right)^{t}$ (see Proposition 13). We conclude that the set of uncovered vertices in a $\left(P_{3}\right)^{3}$-packing of $Q_{n}$ forms a separating family for [ $n$ ], implying that it has size at least $\log n$.

## 3 Perfect $H$-packings of $\left(P_{2|H|}\right)^{n}$

Our main aim in this section is to prove Theorem 3.
Theorem 3. Let $H$ be an induced subgraph of $Q_{k}$ for some $k$. Then $\left(P_{2|H|}\right)^{n}$ can be partitioned into induced copies of $H$, whenever $n$ is sufficiently large.

Recall that a result of Gruslys, Leader and Tomon [7] implies that it suffices to find $l$ - and $(1 \bmod l)$ partitions into copies of $H$. Before stating their result precisely, we introduce some notation.

Let $A$ be a set. We identify $A^{n} \times A^{m}$ with $A^{n+m}$ (whenever $m$ and $n$ are positive integers). Thus, for any $x \in A^{n}$ and $y \in A^{m}$, we treat $(x, y)$ as an element of $A^{n+m}$. Given a set $X$ in $A^{n}$, and a permutation $\pi:[n] \rightarrow[n]$, we define $\pi(X)$ to be the image of $X$ under the permutation of the coordinates according to $\pi$. In other words, $\pi(X)=\left\{\left(x_{\pi(1)}, \ldots, x_{\pi(n)}\right):\left(x_{1}, \ldots, x_{n}\right) \in X\right\}$. Finally, given sets $X$ in $A^{m}$ and $Y$ in $A^{n}$ where $m \leq n$, we say that $Y$ is a copy of $X$ if $Y=\pi(X \times\{y\})$ for some $y \in A^{n-m}$.

Theorem 5 (Gruslys, Leader, Tomon [7]). Let $\mathcal{F}$ be a family of subsets of a finite set A. If there exists $l$ for which $\mathcal{F}$ contains an $l$-partition and $a(1 \bmod l)$-partition of $S$, then there exists $n$ for which $S^{n}$ admits a partition into copies of elements in $\mathcal{F}$.

The task of finding an $l$-partition is quite simple. In fact, it follows directly from the analogous result in [5] and the fact that $\left(P_{2 l}\right)^{n}$ can be partitioned into copies of $Q_{n}$. For the sake of completeness, we include the proof here.

Observation 6. Let $H$ be an induced subgraph of $Q_{k}$ for some $k$. Then there is an $|H|$-partition of $\left(P_{2|H|}\right)^{n}$ into induced copies of $H$, for any $n \geq k$.

Proof. Denote $l=|H|$. Note that, since the path $P_{2 l}$ can be partitioned into $l$ edges, its $n$-th power $\left(P_{2 l}\right)^{n}$ can be partitioned into $l^{n}$ induced copies of $Q_{n}$. Thus, it suffices to exhibit an $l$-partition of $Q_{n}$ into induced copies of $H$. Let $X$ be the vertex set of some induced copy of $H$ in $Q_{n}$. We consider the set of all shifts of $X$. For every $u \in Q_{n}$, we note that the set $X+u=\{x+u: x \in X\}$ (addition is done coordinate-wise and modulo 2) is an induced copy of $H$ in $Q_{n}$. Consider the collection $\left\{X+u: u \in Q_{n}\right\}$. By symmetry, every vertex in $Q_{n}$ is covered by the same number of sets. Furthermore, there are $2^{n}$ such sets, each covers $l$ points, so the number of times each vertex is covered is $\frac{2^{n} l}{2^{n}}=l$. So, we found an $l$-partition of $Q_{n}$ into induced copies of $H$.

The next task, of finding a $(1 \bmod l)$-partition of $\left(P_{2 l}\right)^{n}$ into copies of $H$, is significantly harder. Unlike Observation 6, we cannot directly apply the analogous result of Gruslys [5]. Instead, we adapt his method to our setting.

Theorem 7. Let $H$ be a non-empty induced subgraph of $Q_{k}$ for some $k$. Then there is a $(1 \bmod l)$ partition of $\left(P_{2 l}\right)^{k}$ into induced copies of $H$.

We note that in Theorem 3, unlike Observation 6, there is no restriction on the order of $H$.
Before proceeding to the proof of Theorem 7, we show how to prove Theorem 3 using Observation 6 and theorem 7 .

Proof of Theorem 3. Denote $l=|H|$. Note that it suffices to show that for some $n$ the graph $\left(P_{2 l}\right)^{n}$ can be partitioned into induced copies of $H$. Recall that $H$ is an induced subgraph of $Q_{k}$, for some $k$. By Theorem 7, there is a $(1 \bmod l)$-partition of $A=\left(P_{2 l}\right)^{k}$ into induced copies of $H$. By Observation 6 there is an $l$-partition of $A$ into induced copies of $H$. Hence, by Theorem 5 there exists $n$ for which there is a perfect $H$-packing of $A^{n}=\left(P_{2 l}\right)^{k n}$, as required.

We now proceed to the proof of Theorem 7 .

Proof of Theorem 7. We shall prove the following slightly stronger claim: if $H$ is a non-empty induced subgraph of $Q_{k}$, then there is a $(1 \bmod r)$ partition of $\left(P_{2 l}\right)^{k}$ into isometric copies of $H$.

Let us first explain briefly what we mean by an isometric copy of $H$ in a graph $G$. We consider the graphs $Q_{k}$ and $G$ together with the metric coming from the graph distance. An isometric copy of $H$ is the image of $H$ under an isometry $f: Q_{k} \rightarrow G$ (here we fix a particular embedding of $H$ in $\left.Q_{k}\right)$.

Define $H_{-}$and $H_{+}$as follows.

$$
\begin{aligned}
H_{-} & =\left\{u \in Q_{k-1}:(u, 0) \in H\right\} \\
H_{+} & =\left\{u \in Q_{k-1}:(u, 1) \in H\right\} .
\end{aligned}
$$

We prove the claim by induction on $k$. It is trivial for $k=1$ (then $H$ is either a single vertex or an edge), so suppose that $k \geq 2$ and the claim holds for $k-1$. Note that we may assume that $H_{-}$and $H_{+}$are both non-empty. We shall show that $\left(P_{2 l}\right)^{k}$ has a $(1 \bmod l)$-partition into isometric copies of $H$.

We denote the vertices of $P_{2 l}$ by $\{0,1, \ldots, 2 l-1\}$. Let $p \in[2 l-2]$. By induction, there is a collection of isometric copies of $H_{-}$in $\left(P_{2 l}\right)^{k-1} \times\{p\}$ such that each point is covered $(1 \bmod l)$ times. Let $A$ be the vertex set of such a copy of $H_{-}$. Then there is an isometric copy of $H$ in $\left(P_{2 l}\right)^{k-1} \times\{p, p+1\}$ whose intersection with $\left(P_{2 l}\right)^{k-1} \times\{p\}$ is $A$. It follows that there exists a collection $\mathcal{H}$ of isometric copies of $H$ in $\left(P_{2 l}\right)^{k-1} \times\{p, p+1\}$ for which every point in $\left(P_{2 l}\right)^{k-1} \times\{p\}$ is covered $(1 \bmod l)$ times. Let $\mathcal{H}^{\prime}$ be the collection of isometric copies of $H$ in $\left(P_{2 l}\right)^{k-1} \times\{p-1, p\}$, which is the image
of $\mathcal{H}$ under the map from $\left(P_{2 l}\right)^{k-1} \times\{p, p+1\}$ to $\left(P_{2 l}\right)^{k-1} \times\{p-1, p\}$ obtained by changed the last coordinate from $p+1$ to $p-1$.

Denote by $\mathcal{H}_{p}$ the collection $(l-1) \mathcal{H}+\mathcal{H}^{\prime}$ (i.e. each copy of $H$ in $\mathcal{H}$ is taken $l-1$ times). $\mathcal{H}$ is a collection of copies of $H$ in $\left(P_{2 l}\right)^{k-1} \times\{p-1, p, p+1\}$ which we view as a collection of copies of $H$ in $\left(P_{2 l}\right)^{k}$. For every $x \in\left(P_{2 l}\right)^{k}$, the number of times $x$ is covered is

$$
w_{p}(x)= \begin{cases}(1 \bmod l) & x \in\left(P_{2 l}\right)^{k-1} \times\{p+1\} \\ (-1 \bmod l) & x \in\left(P_{2 l}\right)^{k-1} \times\{p-1\} \\ (0 \bmod l) & \text { otherwise }\end{cases}
$$

Let $\mathcal{G}$ be the collection of isometric copies of $H$ obtained by taking $i$ copies of $\mathcal{H}_{2 i}$ and $\mathcal{H}_{2 i-1}$ for each $i \in[l-1]$. We show that every vertex in $\left(P_{2 l}\right)^{n}$ is covered $(1 \bmod l)$ time by $\mathcal{G}$. Let $x \in\left(P_{2 l}\right)^{k-1}$. Then $(x, 0)$ and $(x, 1)$ are covered $(1 \bmod l)$ times (they get non zero weight only in $\mathcal{H}_{1}$ and $\mathcal{H}_{2}$ respectively). The vertices $(x, 2 i)$ and $(x, 2 i+1)$ (where $i \in[l-2])$ are covered $(-i \bmod l)$ times by $\mathcal{H}_{2 i-1}$ and $H_{2 i}$ respectively, and $(i+1 \bmod l)$ times by $H_{2 i+1}$ and $H_{2 i+2}$, so in total they are covered $(1 \bmod l)$ times. Finally, $(x, 2 l-2)$ and $(x, 2 l-1)$ are covered $l-1$ times by $H_{2 l-3}$ and $H_{2 l-2}$ respectively, so the number of times they are covered is $(-(l-1) \bmod l)=(1 \bmod l)$.

## 4 Almost partitioning the hypercube into powers of a path

Our main aim in this section is to prove Theorem 4.
Theorem 4. For any $l$ and $t$, there is a packing of $Q_{n}$ into induced copies of $\left(P_{l}\right)^{t}$, for which at most $O\left(n^{t-1}\right)$ vertices are uncovered.

Before proceeding to the proof, we make several observations and mention a result that we shall use. The following observation makes use of the fact that $Q_{n}$ is Hamiltonian to prove the special case of Theorem 4 where $l$ is odd and the requirement that the copies are induced is dropped.

Observation 8. Let $l$ be odd, and let $t$ be a positive integer. Then there exists a $\left(P_{l}\right)^{t}$-packing of $Q_{n}$, that covers all but at most $O\left(n^{t-1}\right)$ vertices.

Proof. It is well known that $Q_{m}$ is Hamiltonian. Therefore, if $l$ divides $2^{m}-1$, then $Q_{m}$ may be partitioned into copies of $P_{l}$ and a single vertex. Note that by the Fermat-Euler theorem, there exists $m$ such that $l$ divides $2^{m}-1$ (take $m=\phi(l)$, where $\phi(n)$ is Euler's totient function, counting the number of integers $p<n$ for which $p$ and $n$ are coprime). It follows that all but at most $2^{m(t-1)} \cdot\left|[r]^{<t}\right|$ vertices of $\left(Q_{m}\right)^{r}$ can be partitioned into copies of $\left(P_{l}\right)^{t}$. Given any $n$, write $n=r m+a$ where $a<r$. Since we may view $Q_{n}$ as $\left(Q_{m}\right)^{r} \times Q_{a}$, there is a collection of pairwise
disjoint induced copies of $\left(P_{l}\right)^{t}$ that covers all but at most $2^{a+m(t-1)} \cdot\left|[r]^{<t}\right| \leq 2^{m} \cdot n^{t-1}=O\left(n^{t-1}\right)$ vertices.

The following corollary allows us to extend Observation 8 to all $l$.
Corollary 9. Let $l$ and $t$ be integers. Then all but $O\left(n^{t-1}\right)$ vertices of $Q_{n}$ may be partitioned into copies of $\left(P_{l}\right)^{t}$.

Proof. We prove the statement by induction on $i$, the maximum power of 2 that divides $l$. If $i=0$, $l$ is odd, and the statement follows from Observation 8. Now suppose that $i \geq 1$. Write $l=2 k$ and $Q_{n}=Q_{n-t} \times Q_{t}$. By induction, there is a collection of pairwise disjoint copies of $\left(P_{k}\right)^{t}$ that covers all but at most $O\left(n^{t-1}\right)$ vertices in $Q_{n-t}$. Note that the product $P_{k} \times Q_{1}$ is Hamiltonian, i.e. it spans a $P_{2 k}=P_{l}$. We conclude that $Q_{n}$ may be covered by pairwise disjoint copies of $\left(P_{i}\right)^{t}$ and a remainder of at most $O\left(n^{t-1} \cdot 2^{t}\right)=O\left(n^{t-1}\right)$ vertices.

Let $\mathcal{H}_{l}$ be the collection of graphs on $l$ vertices which have a Hamilton path, and let $\left(\mathcal{H}_{l}\right)^{t}=$ $\left\{H_{1} \times \ldots \times H_{t}: H_{i} \in \mathcal{H}\right\}$. We note that the proofs of Observation 8 and Corollary 9 actually give the following slightly stronger statement.

Corollary 10. Let $l$ and $t$ be integers. Then there is a collection of pairwise disjoint copies of graphs in $\left(\mathcal{H}_{l}\right)^{t}$ that covers all but at most $O\left(n^{t-1}\right)$ vertices of $Q_{n}$.

In order to obtain an almost-partition into induced copies of $\left(P_{l}\right)^{t}$, we need two more ingredients. One is the following observation.

Observation 11. Let $H \in H_{l}$. Then $H \times P_{l-1}$ may be partitioned into induced copies of $P_{l}$.

Proof. Denote the vertices of $H$ by $[l]$ and suppose that $(1, \ldots, l)$ is a path in $H$. Similarly, we denote the vertices of $P_{l-1}$ by $[l-1]$. Let $Q_{i}$ be the path $((i, 1), \ldots,(i, l-i),(i+1, l-i), \ldots,(i+$ $1, l-1)$ ), for $i \in[l-1]$ (see Figure 1). It is easy to see that each $Q_{i}$ is an induced $P_{l}$.

The second ingredient is a result of Ramras [13], which states that if $n+1$ is a power of 2 , then $Q_{n}$ may be partitioned into antipodal paths. In particular, we have the following corollary.

Corollary 12 (Ramras [13]). If $n+1$ is a power of 2 , then $Q_{n}$ may be partitioned into induced copies of $P_{n+1}$.

We are now ready to prove Theorem 4.

Figure 1: Illustration of the paths in Observation 11 (vertical lines denote copies of $H$ )

Proof of Theorem 4. Let $m$ be minimal such that $2^{m} \geq l^{2}$. Suppose that $2^{m}=a(\bmod l)$ where $0 \leq a<l$ and write $2^{m}=(l-1-a)(l-1)+b$. Note that $(l-1-a)(l-1)<l^{2}$ so $b>0$, and by choice of $m, b \leq 2 l^{2}$. Furthermore, $b=-1(\bmod l)$. The path $P_{2^{m}}$ can be partitioned into $l-1-a$ copies of $P_{l-1}$ and one copy of $P_{b}$. It follows from Corollary 12 that $Q_{2^{m}-1}$ may be partitioned into induced copies of $P_{l-1}$ and $P_{b}$, implying that $\left(Q_{2^{m}-1}\right)^{2 t}$ may be partitioned into induced copies of $\left(P_{l-1}\right)^{t}$ and $\left(P_{b}\right)^{t}$.

Write $Q_{n}=Q_{n-t\left(2^{m}-1\right)} \times\left(Q_{2^{m}-1}\right)^{2 t}$. Recall that by Corollary $9, Q_{n-t\left(2^{m}-1\right)}$ may be partitioned into copies of graphs in $\left(\mathcal{H}_{b+1}\right)^{t}$ and a remainder of at most $O\left(n^{t-1}\right)$ vertices.

Combining these two facts, we conclude that $Q_{n}$ can be partitioned into copies of graphs isomorphic to $\prod_{i \in[t]}\left(H_{i} \times P_{x}\right)$ (where $H_{i} \in \mathcal{H}_{b+1}$ and $x \in\{l-1, b\}$ ), and a remainder of at most $O\left(n^{t-1} \cdot 2^{t\left(2^{m}-1\right)}\right)=O\left(n^{t-1}\right)$. We claim that if $H \in \mathcal{H}_{b+1}$ and $x \in\{l-1, b\}$, then $H \times P_{x}$ may be partitioned into induced copies of $P_{l}$. Indeed, if $x=b$ then by Observation 11, $H \times P_{x}$ may be partitioned into induced $P_{b+1}$ 's, which may in turn be partitioned into induced $P_{l}$ 's (since, by choice of $b, l$ divides $b+1$ ). A similar argument holds if $x=l-1$ : first note that $H$ may be partitioned into graphs in $\mathcal{H}_{l}$ (since $l$ divides $b+1$ ), and the product of these graphs with $P_{l-1}$ may be partitioned into induced copies of $P_{l}$, by Observation 11. It follows that $Q_{n}$ may be partitioned into induced copies of $\left(P_{l}\right)^{t}$ and a remainder of order at most $O\left(n^{t-1}\right)$.

## 5 A lower bound on the number of uncovered vertices

In this section we prove Theorem 2.
Theorem 2. In every $\left(P_{3}\right)^{3}$-packing of $Q_{n}$, at least $\log n$ points are uncovered.
We start by proving the following propositions that characterises the intersection of a copy of $\left(P_{3}\right)^{t}$ in $Q_{n}$ with a subcube of co-dimension 1 .

Proposition 13. Let $H$ be a copy of $\left(P_{3}\right)^{k}$ in $Q_{n}$. Then the intersection of $H$ with any subcube $S$ of co-dimension 1 is a copy of one of the following graphs: $\emptyset,\left(P_{3}\right)^{k-1}, P_{2} \times\left(P_{3}\right)^{k-1}$ or $\left(P_{3}\right)^{k}$.

Proof. Let $S$ be the vertex set of a subcube of $Q_{n}$ of co-dimension 1. Write $H=H^{\prime} \times P_{3}$, where every $H^{\prime}$ is a copy of $\left(P_{3}\right)^{k-1}$, and denote $H_{i}=H^{\prime} \times\{i\}$ (where $V\left(P_{3}\right)=\{1,2,3\}$. We prove the statement by induction on $k$.

Let $k=1$, then each $H_{i}$ is a single vertex. Without loss of generality, $H_{2}$ is in $S$ (otherwise consider the complement of $S$ ). But then at least one of $H_{1}$ and $H_{3}$ also are in $S$ (because every vertex in $S$ has exactly one neighbour outside of $S$ ). So, without loss of generality, $H_{1}$ is in $S$. It follows that $V(H) \cap S$ is either $H$ or $H_{1} \times H_{2}$, as claimed.

Now suppose that $k \geq 2$. Then by induction, and without loss of generality, the intersection of $S$ with $H_{1}$ is either $H_{1}$ or a copy of $P_{2} \times\left(P_{3}\right)^{k-1}$.

Suppose that the first case holds, i.e. the intersection of $S$ with $H_{1}$ is $H_{1}$. Then, if any vertex in $H_{2}$ is in $S$, all vertices of $H_{1}$ are in $S$ (since every vertex in $S$ has exactly one neighbour outside of $S$ ). In other words, $H_{2}$ is either contained in $S$ or it is contained in $\bar{S}$, the complement of $S$. If the former holds, then, similarly, $H_{2}$ is contained in either $S$ or $\bar{S}$, and if the latter holds then $H_{2}$ is contained in $\bar{S}$ (since every vertex in $H_{2}$ is in $\bar{S}$ and has a neighbour in $S \cap H_{1}$ ). It follows that the intersection of $S$ with $H$ in this case is $H_{1}, H_{1} \times H_{2}$, or $H$, as required.

Now suppose that the second case holds, i.e. the intersection of $H_{1}$ with $S$ is a copy of $P_{2} \times\left(P_{3}\right)^{k-1}$. Then we may write $H_{1}=H^{\prime \prime} \times P_{3}$ where $H^{\prime \prime}$ is a copy of $\left(P_{3}\right)^{k-2}$, and $H^{\prime \prime} \times\{1,2\}$ (where $V\left(P_{3}\right)=$ $\{1,2,3\})$ is the intersection of $H_{1}$ with $S$. Denote $H_{i, j}=H^{\prime \prime} \times\{i\} \times\{j\}$. So $H_{1,1}$ and $H_{1,2}$ are in $S$ and $H_{1,3}$ is in $\bar{S}$. It follows that $H_{2,2}$ is in $S$ (otherwise some vertex in $H_{1,2}$ would have two neighbours in $\bar{S}$ ); $H_{2,1}$ is in $S$ (otherwise a vertex of $\bar{S} \cap H_{2,1}$ would have two neighbours in $S$ ); and $H_{2,3}$ is in $\bar{S}$. Similarly, $H_{3,1}$ and $H_{3,2}$ are contained in $S$ and $H_{3,3}$ is in $\bar{S}$. It follows that the intersection of $H$ with $S$ is a copy of $P_{2} \times\left(P_{3}\right)^{k-1}$.

We are now ready for the proof of Theorem 2

Proof of Theorem 2. Let $\mathcal{H}$ be a collection of pairwise disjoint copies of $\left(P_{3}\right)^{3}$ in $Q_{n}$ and let $S$ be a subcube of co-dimension 2 in $Q_{n}$, and let $S^{\prime}$ be a subcube of co-dimension 1 in $Q_{n}$ that contains $S$. Let $H \in \mathcal{H}$. Then, by Proposition 13, the intersection of $H$ with $S^{\prime}$ is either the empty set or it is the disjoint union of up to three copies of $\left(P_{3}\right)^{2}$. It follows from Proposition 13 that the intersection of $H$ with $S$ is the disjoint union of copies of $P_{3}$. In particular, since 3 does not divide the order of $S$, at least one vertex in $S$ is not covered by $\mathcal{H}$.

Let $\mathcal{P}$ be the collection of subsets of $[n]$ that correspond to vertices of $Q_{n}$ that are not covered by $\mathcal{H}$ (where we consider the usual map between $Q_{n}$ and $\mathcal{P}([n])$ that sends a vertex $u$ in $Q_{n}$ to the set of
elements in $[n]$ whose coordinates in $u$ is 1 ). We claim that the collection $\mathcal{P}$ is a separating family for $[n]$, namely, for every distinct elements $i$ and $j$ in $[n]$, there is a set $A \in \mathcal{P}$ that contains $i$ but not $j$. Indeed, given distinct $i$ and $j$ in $[n]$, let $S$ be the subcube of co-dimension 2 of vertices whose $i$-th coordinate is 1 and whose $j$-th coordinate is 0 . Then $S$ contains a vertex which is uncovered by $\mathcal{H}$. This vertex corresponds to a set in $\mathcal{P}$ that contains $i$ but not $j$. It is a well known fact that a family that separates $[n]$ has size at least $\log n$. It follows $\mathcal{P}$ has size at least $\log n$, implying that at least $\log n$ vertices of $Q_{n}$ are not covered by $\mathcal{H}$.

We remark that by considering $\left(P_{3}\right)^{2 k+1}$ packings of $Q_{n}$, the number of missing vertices can be shown to be at least $(1+o(1)) k \log n$ (since the subsets corresponding to the missing vertices form a separating system for $\left.[n]^{(k)}\right)$.

## 6 Concluding remarks

We showed that if $H$ is an induced subgraph of $Q_{k}$ then there exists a packing of $Q_{n}$ into induced copies of $H$, which misses at most $O\left(n^{c}\right)$, for $c=c(H)$. On the other hand, we showed that the error term cannot be replaced by anything smaller than $\log n$ (or, as we remarked in Section 5 by $c \log n$ for any $c$ ). It would be very interesting to close the gap between the two bounds.

We believe that the upper bound, of $O\left(n^{c}\right)$ is closer to the truth, i.e., we believe that there exist graphs $H$ for which at least $\Omega\left(n^{c}\right)$ vertices remain uncovered in any $H$-packing of $Q_{n}$. More specifically, it seems plausible to believe that every $\left(P_{3}\right)^{k}$ packing of $Q_{n}$ leaves at least $\Omega\left(n^{k-1}\right)$ vertices uncovered. We thus state the following question.

Question 14. Is there $a\left(P_{3}\right)^{k}$ packing of $Q_{n}$ for which the number of uncovered points is at most $o\left(n^{k-1}\right)$ ?

In this paper we are interested in $H$-packings of $Q_{n}$, which can be viewed as $\left(P_{2}\right)^{n}$. It would be interesting to consider the more general setting of $H$-packings of $G^{n}$. We mention a conjecture of Gruslys [5].

Conjecture 15 (Gruslys [5]). Let $G$ be a finite vertex-transitive graph, and let $H$ be an induced subgraph of $G$. Suppose further that $|H|$ divides $|G|$. Then for some $n$ there is a perfect $H$-packing of $G^{n}$.

We note that the conjecture does not hold if we drop the vertex-transitivity (see Proposition 9 in [5]).

In Section 1, we mentioned a recent result of Tomon [14] who proved that if $P$ is a poset with a minimum and a maximum, then the Boolean lattice $2^{[n]}$ can be partitioned into copies of $P$ and a
remainder of at most $c$ elements, where $c=c(P)$. It would be interesting to generalise his result to all posets $P$, dropping the requirement of the existence of a minimum and a maximum. This would resolve a conjecture of Gruslys, Leader and Tomon [7].

Conjecture 16 (Gruslys [7]). Let $P$ be a poset. Then the Boolean lattice $2^{[n]}$ can be partitioned into copies of $P$ and a remainder of at most $c=c(P)$ elements.

Finally, we mention a question about Hamilton paths of $Q_{n}$. Recall that in order to prove that $Q_{n}$ can be almost partitioned into induced copies of $\left(P_{l}\right)^{t}$, we first proved this statement without requiring the copies to be induced. That followed easily from the fact that $Q_{n}$ is Hamiltonian. We then used such a partition to obtain a partition of $Q_{n}$ into induced copies of $\left(P_{l}\right)^{t}$. A more direct approach could be to find a Hamilton path $P$ in $Q_{n}$ for which every $l$ consecutive vertices induced a $P_{l}$. We were unable to determine if such a Hamilton path exists. We thus conclude the paper with the following question.

Question 17. Let $l$ be integer. Is it true that for sufficiently large $n$, there is a Hamilton path $Q_{n}$ for which every l consecutive vertices induce a $P_{l}$ ?
