4 Introduction

This report provides details of work performed on the SEPA contract to ENSIS Ltd. involving the preparation and analysis of historic (September 1994 – August 2010) Environmental Change Network diatom samples from the River Clyde at the Tidal Weir.

Diatoms were collected from the site by SEPA, forwarded to ENSIS Ltd and prepared for analysis following protocols described in the United Kingdom Environmental Change Network's "Protocols for Standard Measurements at Freshwater Sites" (Sykes *et al.*, 1999). Samples were taken at the site at various times of year and a full list of those that have been received by ENSIS is provided in Appendix 1. For this project, in order to minimise any inter-seasonal variability in the time-series, Kate Arnold from SEPA selected a subset of 16 summer samples for analysis, all collected between late July and early September.

Approximately 400 diatom valves were counted per sample by Gina Clarke using a light microscope with phase contrast at 1000x magnification. Count data were recorded on a spreadsheet and transferred to ENSIS where they have been added to the ECN diatom database and have also been provided to SEPA.

The diatom count data was run through the DARLEQII program (Kelly *et al*, 2011) in order to generate Trophic Diatom Index (TDI), Ecological Quality Ratio (EQR) and status class values (high, good, moderate, poor, bad) for each sample. Alkalinity values for the calculations were provided by SEPA for all samples except the earliest three in the time-series, for which the average from all samples was used. Both TDI3 and TDI4 scores were calculated for all samples and the scores reported here. Table 1 is taken from the DARLEQII user guide (Kelly *et al*, 2011) and describes the output fields provided in the results section for the site below. Electronic copies of the full DARLEQII program output have been provided to SEPA.

Table 1 Trophic Diatom Index (TDI) calculation output field descriptions

| Field name | Field description |
|-------------------|--|
| Sample sum | Sum of the counts or percentages of all taxa in a sample |
| Sum TDI3/4 | Sum of the counts or percentages for all taxa in a sample that are matched to taxa in the master taxon list and included in the TDI calculation. If all taxa are matched this will be the same as the Sample sum. Comparison of these two fields will indicate if there are important taxa present in the sample but not included in the status calculations |
| TDI3/4 | TDI score for each sample using the revised TDI taxon scores for rivers. |
| eTDI3/4 | Expected TDI score for each sample according to site-specific prediction (rivers) |
| EQR TDI3/4 | Ecological Quality Ratio for each sample based on predicted TDI for observed alkalinity and season (rivers). |
| Class | Status class based on EQR |
| % Planktic | Percentage of planktic diatoms in the sample. These are excluded from the status calculations |
| % Motile | Percentage of the motile diatoms in the sample |
| %OrganicTolerant | Percentage of organic pollution tolerant diatoms in the sample |
| %Saline | Percentage of diatoms tolerant of slightly saline waters |
| Comments | List of any warning messages generated during calculations for individual samples. |

5 Site R13. Lower Clyde

Figure 1 River Clyde. Looking south-east from the bridge on the A8. Image from Google Streetview

5.1 Site Description

“The catchment area of the River Clyde is about 2000km² and the river changes in character a great deal in its 121km journey to the tidal weir in Glasgow. In its upper reaches, it is used to fill the Daer reservoir which supplies drinking water to much of South Lanarkshire; there is also sheep farming and commercial afforestation in this part of the catchment. The river is joined by tributaries of various sizes and quality reflecting the land uses of their catchments: there is much opencast coal mining in some, whilst others are urban or agricultural. The Clyde passes through a fertile valley in its middle reaches where there is extensive market gardening, fruit growing and garden centres. In its lower reaches the river receives a considerable amount of treated sewage effluent from large regional sewage works. The river is quite sluggish in its flow because of the flat landscape. As a result of this and the BOD of the effluents, there is serious oxygen depletion in the lower reaches during the summer months.

The ECN sampling site is situated in the lowest reach, where average flow is 41 cumecs.”
[\(ECN website, 2017\).](#)

5.2 Diatom Count Summary

16 ECN diatom samples from the location S01 in the River Clyde (Table 2.) were either retrieved from the UCL archive or prepared into diatom slides and counted using standard methods (Battarbee *et al.* 2001). A percentage abundance time-series plot of diatom species was generated using the program C2 (Juggins, 2007), and is shown in Figure 2. It includes all species occurring at abundances greater than two percent. Diatom species recorded and the number of samples in which they occurred are presented in Table 3. and Figure 3. Trophic Diatom Index (TDI) scores (Kelly *et al.*, 2008) were calculated for each sample. TDI3 scores are provided in Table 4. and TDI4 scores in Table 5. No samples were collected in 2004.
