1 ABSTRACT

2

The literature on ride-hailing has experienced rapid growth in recent years, with an accent on industrialized cities, mainly in the United States and Europe. Previous research has identified the characteristics and preferences of ride-hailing adopters in a handful of cities. However, given their marked geographical focus, whether such findings are relevant and applicable to the practice of transport planning and regulation in cities in the Global South remains largely untested.

8 This paper examines ride-hailing in the Metropolitan Area of Mexico City. We build on 9 statistical modelling informed by the Mexico's household travel survey from 2017 to determine 10 the main drivers for ride-hailing adoption, unpack ride-hailing user characteristics, and understand 11 how they differ from other transport users in the local context. We use findings to discuss the 12 implications of ride-hailing for urban mobility in one of the largest cities in Latin America.

Recognizing that the trajectory of adoption and development of app-based urban transport services differs from those followed in the United States and Europe, the paper hypothesizes that ride-hailing usage in a context such as Mexico may be mediated by social issues such as the perception of crime, risk of sexual harassment in public transportation, and lack of flexibility and quality in other modes. Such challenges are frequently experienced by women in this and similar contexts as documented by the literature.

Our findings shed light on the complex role of gender and care relationships play in the 19 adoption of on-demand transportation services. Relevant findings suggests that variables such as 20 age, education and income have a positive effect on ride-hailing adoption, in line with the existing 21 literature. Also in line with current literature, we find that ride-hailing in Mexico City is 22 23 instrumental for leisure and health trips. However, when considering gender, and the links between gender and care responsibilities, findings show that women in households with a higher number 24 of elders depend more on on-demand transport. These results are novel in the context of the ride-25 26 hailing literature and suggest areas for further exploration in similar contexts to inform discussions about the role of these travel alternatives for women and their ability to navigate the city. 27

28

29 Keywords: Gender, Mexico, Ride-hailing, TNC.

1. Introduction

1

2

3 Transport Network Companies (TNCs) are rapidly transforming the way mobility needs 4 are being met across the globe. Also known as ride-hailing, on-demand services, and platformbased mobility services, TNC companies provide on-demand services by matching passengers 5 6 needing a ride and drivers through smart phones and GPS enabled applications. Entering in 2013, 7 TNCs have rapidly made their way into emerging and large cities in Latin America (Latam). TNCs 8 services have been argued to offer several advantages to other modes, including relative ease use, 9 seamless payment options, and security features. System features such route optimization, and 10 surge pricing, that work together to direct drivers to high demand areas, have been argued to increase efficiency and reduce uncertainty over travel times and the hassle of parking (Lesteven 11 and Samadzad, 2021). Additionally, by offering service in hours and places lacking public transit, 12 they potentially increase mobility options in areas with poor public transit coverage, reduce the 13 need for private auto ownership and usage, and may increase employment opportunities due to 14 low barriers to entry (Azuara et al., 2019). 15

Nevertheless, policymakers have raised concerns about the possible risks for sustainable 16 transport development, spurring debates around the potential negative externalities of rapidly 17 growing ride-hailing on urban transportation systems, such as increases in demand for individual 18 forms of transport, vehicle miles traveled, and congestion. Ride-hailing's virtually constant 19 availability, demand responsiveness, and geographic coverage, unbound from routes and stations, 20 fixed schedules (Alemi et al., 2018a; Dias et al., 2017; Etminani-Ghasrodashti and Hamidi, 2019), 21 has also raised concerns around its impacts on public transit ridership and active modes of transport 22 23 such as walking and cycling (Gabel, 2016).

Several studies in the developed countries context have looked extensively at factors 24 influencing ride-hailing and the way people are interacting with the services. This body of 25 literature (Alemi et al., 2018a; Dias et al., 2017; Etminani-Ghasrodashti and Hamidi, 2019) finds 26 that comparatively younger users are more likely to use ride-hailing, and that the adoption of the 27 service is influenced by levels of engagement with technology, as well as direct or indirect impacts 28 29 of the built environment (Alemi et al., 2018c). However, large gaps in the research exist regarding the factors influencing the adoption and intensity of ride-hailing research in developing countries 30 context where there are stark differences in levels of economic development, crime, and quality of 31 32 transport infrastructure.

Many patterns of the variables influencing ride-hailing adoption are expected to be similar in the developed and developing world. For example, it is expected that younger people, highly educated people, or people with high income are using ride-hailing services more frequently. Nevertheless, a key difference to be expected is the role of gender. Current literature (not specific to the Mexican or Latam context) consistently argues that being a female has not impact on ridehailing usage, and even that males are more likely to adopt the service. As we will show in this paper, gender is key to understand the ride-hailing trajectory in Mexico City.

In this paper, we develop a conceptual framework for ride-hailing adoption drawing on existing literature and adapting it to the particularities of Mexico City and the developing country context. The framework is empirically analyzed using a set of categorical models identifying variables that explain ride-hailing trips, as well as the variables that distinguish ride-hailing adopters from users of other transport modes like the car, public transport, or walking. Findings in the paper seek to contribute to current debates about the determinants of the use of ride-hailing and to provide insights for decision-making and policy in the local context of Mexico City. 1 2

2. Literature Review

3 Research to-date on ride-hailing has focused on several fronts, including identifying the 4 factors influencing its adoption and usage patterns (Alemi et al., 2018a), measuring its impacts on travel behavior, and understanding changes in vehicle kilometers traveled (Alemi et al., 2019; 5 6 Tirachini and del Río, 2019), among others. A more recent strand of literature examines the effects 7 of ride-hailing's impacts on public transit use and modal substitutions. For example in Toronto, 8 Canada, Young et al., (2020) estimate the degree to which ride-hailing trips complement or 9 substitute public transit (Young et al., 2020). They modeled three outcomes based on the difference in travel times for ride-hailing trips and their transit counterpart, where simulations were used to 10 estimate travel times. The authors found that 31% of ride-hailing trips have a similar duration to 11 transit trips, suggesting competition. Additionally, 27% of the ride-hailing trips were more than 30 12 minutes faster than the transit alternative. The authors argue that, for these cases, ride-hailing is 13 filling a gap given that these trips are too long for transit. The paper recommends creating a tax 14 for ride-hailing trips that compete directly with transit. For Bogotá, Colombia, a study (Oviedo et 15 al., 2020) simulate trip costs for origin destination pairs in the household surveys, and used stated-16 preference surveys to model potential modal shifts between public transit, private cars and TNCs 17 under a range of scenarios. They find that nearly one-third of public transportation trips could be 18 at risk of shifting to ride-hailing under the current public transportation fare scheme and mean 19 travel times, and that an important share of the population is expected to be willing to pay more to 20 reduce travel times. 21

In the next subsection we present a general overview of research on ride-hailing adoption 22 highlighting the main variables that literature considers to be instrumental for ride-hailing trips. 23 This way, we can clearly identify if there are differences or similarities with results from our 24 models presented in section 5. In section 2.2 we move to an exploration of the gender dimension 25 of ride-hailing and show current literature (mainly from developed countries) is consistently saving 26 that males have higher propensity to adopt ride-hailing or that there is not a gender difference at 27 all. We separate results related to gender given that one of the main contributions of the paper is 28 29 that in the context of Mexico City, and probably in other cities in the region, gender (being a female) is instrumental for adoption. This contrasts with mainstream literature. 30

33 34

2.1. Ride-hailing adoption

Several authors have developed conceptual frameworks (Acheampong et al., 2020; 35 Etminani-Ghasrodashti and Hamidi, 2019; Lavieri and Bhat, 2019) intended to explain the 36 complexities of ride-hailing adoption. In the developed country context, a study in the Seattle 37 Metropolitan Area (Dias et al., 2017) modeled "ride-hailing frequency" and "car-sharing 38 frequency." Albeit analyzing data in the early stages of operation of TNCs, they found that ride-39 hailing users are mainly highly educated, young, high income, and living in high-density areas-40 findings that have persisted in much of the subsequent ride-hailing research over time. Using 41 Structural Equation Models SEM in the Dallas-Fort Worth Metropolitan Area (Lavieri and Bhat, 42 2019), a study on ride-hailing adoption and usage, showed that low residential density and 43 concerns about privacy (mainly for non-Hispanic whites) have negative impacts on the frequency 44 of use. Alemi et al. (2018a) studied ride-hailing adoption in the state of California, considering a 45 diverse set of behavioral variables such as lifestyles, attitudes towards technology and pro-46

environmental policies, and sociodemographic variables. The model also accounted for
accessibility, a mix of land use, and neighborhood type (urban, suburban, or rural). Like Dias et
al. (2017), they find that ride-hailing users are young (older millennial) and well-educated people.
However, their models reveal a more nuanced picture identifying clusters of adopters by their
socioeconomic characteristics and land use characteristics of their residence and then analyzing
how these factors influence their ride-hailing frequency.

7 First, they identify three main clusters of adopters: 1) high frequency adopters, who tend 8 to be highly educated, childless, independent millennials, living in high-quality transit 9 neighborhoods, 2) mid-level adopters-affluent millennials (or older Generation X) living with their families, who usage is often influenced by land-use mix, use of smartphones, and long-distance 10 business trips, and 3) low-level adopters, who are less affluent, with lower educational attainment, 11 and tend to live in rural areas and for whom the ride-hailing use is constrained by income, long-12 distance non-car business trips (often flights), and transit accessibility. The second extension 13 shows that the use of smartphones and the propensity to take long-distance trips by plane is 14 positively related to both adoption and more usage of ride-hailing, while willingness to pay more 15 to reduce travel time and increased land use density (in residence) are related to more frequent 16 17 usage.

Tirachini and Del Río (2019) modeled "frequency of use" and "occupancy rate" of ride-18 hailing in Santiago de Chile using ordered logistic models (Tirachini and del Río, 2019). Some 19 results are consistent with previous literature. For example, they find that younger people are more 20 likely to use ride-hailing more often. Nevertheless, contrary to findings in the developed country 21 context (Alemi et al., 2018a; Tirachini, 2019), car availability did not explain frequency (when 22 controlling for age and income). In metropolitan Teheran, Iran, a study (Etminani-Ghasrodashti 23 and Hamidi, 2019) also modeled the frequency of use per month using a Structural Equation Model 24 (SEM), finding cost effectiveness, security, anti-shared mobility, and technology adoption are 25 essential determining factors. The study suggests that increased car usage is associated with more 26 ride-hailing usage, and that ride-hailing does not necessarily imply fewer car-based trips. 27

Turning to a developing country, another study (Acheampong et al., 2020) conducted in Accra and Kumasi (Ghana) also using SEM showed that, similar to other studies previously referenced, that ride-hailing is mostly used for occasional trips (51%); however work and school trips also represented a substantial share of the trips (41%). Nevertheless, in contrast to other studies, the main travelers are not located on the urban side of the city but in the inner-suburban and outer-suburban localities.

2.2. Gender, transportation, and ride-hailing research

Differences in socio-economic conditions and social norms among men and women play a 38 significant role in determining travel behavior (Curtis and Perkins, 2006). These differences are 39 even more marked in the developing country context where women take on more household and 40 care related work and are less likely to participate in the labor market. When they do work outside 41 the home, they are more likely to work close to their home to allow time for care-related travel and 42 domestic responsibilities. Moreover, women trips tend to make more chained trips involving 43 multiple stops and transfers compared to men, report making a significant number of trips for 44 family and personal business (Schintler et al., 2000), and are more likely to travel to accompany 45 others (such as children or the elderly), or to buy groceries and medicines, and carry packages, 46

strollers and wheel chairs, to comply with their care work duties (Hasson and Polevoy, 2011; Soto
Villagrán, 2019). Lower income women tend to access to slower and lower quality modes
compared to men, relying extensively on walking and public transit, even when a private vehicle
is available in the household (Peters, 2013). In addition to having distinct transport needs, women
are frequently victims of sexual harassment and other crimes, often report feeling unsafe when
using public transport systems (Gardner et al., 2017; Gekoski et al., 2017)

7 In LAC, public transit systems tend to be characterized as highly informal (Tun et al., 2020), 8 and often lack defined stops, or security protocols and mechanisms in place to report crimes and incidents of harassment (World Bank Group and UFGE, 2020). They are also characterized as 9 having higher rates of sexual harassment and assaults (FIA Foundation and CAF, 2017). Research 10 on the role of investments in formal mass transit systems such as BRTs and metros that reduce 11 travel times and include features to improve security such as cameras, guards and police at stations, 12 and mechanisms for reporting incidents in Latin America has found that women living within 13 walking distance to such systems are more likely to participate in the labor market and be employed 14 suggesting that travel time savings and increased security can have an important role in improving 15 women's access to jobs (Martínez et al., 2018). 16

Many studies have explored the role of gender in adoption and frequency of ride-hailing. Research on ride-hailing has explored gender in two main ways i) including gender in the analysis as a control, but not as a key variable of interest, or ii) including it as variable of interest, but finding that men are more likely to adopt ride-hailing than women, in opposition to what we hypothesize for the case of Latam. Research finding that men are more likely adopters than females are based in the USA and Canada, while there is one study showing a reverse effect in a developing country. There is little research on gender and ride-hailing in developing country context.

Descriptive research comparing socioeconomic characteristics of ride-hailing with taxis and public transit users in San Francisco (Rayle et al., 2016), although not focused on gender, presented descriptive statistics showing that males (60%) adopting ride-hailing services at higher rates than females (40%). A similar gender pattern for taxi users (who use them at least once a week) was found (42% for females and 56% for males), a striking result when considering 49% the population of San Francisco are females and 51% are males.

Alemi et al., (Alemi et al., 2018a) in their study on ride-hailing adoption and use in California 30 found that women were slightly more likely to adopt ride-hailing compared to men and that on-31 32 demand services are higher among women, although it was not an important predictor compared to other socio-economic and built environment factors studied. An extension of the previous 33 discussed article used Latent Class Analysis LCA (Alemi et al., 2018c) to create segments of users 34 and explain factor influencing ride-hailing through a class membership model. Gender was not 35 included in the class membership model of the LCA as was the case of the personal and 36 demographic variables stage of life, marital status, income, occupation, education, and 37 neighborhood type. Despite gender not playing a role in the model or the research, the authors 38 mention that the share of females is slightly higher than the share of male in the class with more 39 ride-hailing usage. 40

A more recent strand of research has found that males are more likely to use ride-hailing when compared to females. For example, research in the United States using National Household Travel Survey from 2017 (Mitra et al., 2019) and a logit model, found that mean were 16% more likely than women to (odds ratio of 1.159 for males (compared to females)) to use ride-hailing services. The study also highlights that men with medical conditions are more likely to engage in ridehailing than females. A study in the Dallas-Fort Worth-Arlington Metropolitan Area (DFW) of Texas (Lavieri and Bhat, 2019) used a convenience sample of 1,607 respondents gathered through a web-based instrument and, using a structural equation model, finds that "variety-seeking attitudes" is positively associated with ride-hailing frequency of use. The gender dimension comes into play in a mediation through this latent, where males have higher levels of variety-seeking attitudes. In contrast, a recent study in Tehran (Lesteven and Samadzad, 2021) using survey data and ordered logit models shows that men are less likely to use ride-hailing, though the main determinants of adoption are income and having a smartphone.

8 In the LAC region, a study in the city of Santiago de Chile used a difference-in-difference model to establish the effect of ride-hailing on drunk- driving fatal traffic accidents and fatalities 9 10 considering differentiating effects of males and females (Lagos et al., 2019). The results indicate that ride-hailing has decreased accidents and fatalities for all users, but mainly for female 11 passengers, as well as among male drivers working at night. Finally, recent research in three 12 Mexican cities (Mérida, Toluca de Lerdo, and Aguascalientes) focusing on exclusive and pooled 13 services and using descriptive statistics from a survey to users of a Transportation Network 14 Company operating in the country (Moody et al., 2021), shows that the share of males (67.7%) 15 using express services is higher than the share of females (32.3%). Despite the handful of studies 16 that have findings regarding how gender interplays with ride-hailing adoption, very few studies 17 explore the role of gender and ride-hailing usage in depth in the Latin American or developing 18 country context. 19

20 21

22

3. Background and conceptual framework

23 The Latin American and Caribbean region (LAC) suffers from some of the highest levels of social and economic income inequality and poverty rates in the world and is highly urbanized. 24 With average Gini index of 42 percent and poverty rates of around 30% (CEPAL, 2015), more 25 than 80 percent the population in the countries live in cities. Urban areas in the region tend to be 26 characterized by low quality and a lack of universal coverage of transport infrastructure services, 27 particularly in lower income zones. Gaps in infrastructure investments combined with rapid 28 29 motorization and urbanization have led to high levels of urban sprawl and congestion, and long travel times of up to 2 to 3 hours per day, and to lower levels of access and mobility, particularly 30 for the urban poor. 31

32 A sprawling metropolis, Mexico City has undergone explosive urbanization; its population nearly doubled in the span of four decades, rising from 13 to 22 million between 1980 to 2019. 33 Over this period much of the population moved to suburban locations while jobs remained 34 centralized (Guerra et al., 2018) generating long commuting times and dependency on vehicles. 35 The city suffers paralyzing levels of congestion, driven by high rates of motorization, a fragmented 36 and largely uncoordinated public transit system, and long trip distances between origins and 37 destinations. There are over 5 million registered vehicles and 350,000 registered motorcycles in 38 the city (Flannery, 2019). Near 37% of the total trips in the city during a typical day are made by 39 public transport, however, most of the trips are made using small informal operators (OECD, 40 2019). While the share of trips made by ride-hailing in Mexico City as well as other cities in the 41 LAC region is still low, the individual nature of the trips combined with the fact that ride-hailing 42 vehicles travel without a passenger for some portion of the trips, raises concerns around the level 43 of vehicle kilometers traveled and potential impacts on congestion and public transit ridership, 44 making understanding the patterns of use critical to planning and policies aimed at reducing their 45 potential externalities while enhancing their value to consumers. 46

Crime and sexual harassment, which disproportionately affect women, are pervasive issues 1 2 in Mexico City's transportation system. By 2008, 90% of women had experienced some sort of sexual violence while using public transportation in Mexico City. A recent study (Soto Villagrán 3 4 et al., 2019) found that in some stations near 50% of women have received obscene words when using public transport, and, in one station, 6.7% have been photographed without consent. It has 5 spurred the implementation of innovative policies like the 'pink transportation program' (Dunckel-6 Graglia, 2013), a transport service exclusive for women decorated with images of famous women 7 8 intended to foster self-esteem, notice violence, and encourage the actions for and by women. The 9 Pink Transportation program has been complemented with broader support to victims and was 10 expanded to cabs.

Ride-hailing has been operating in Mexico City since 2013 with Cabify, the first TNC in 11 arriving the city. Cabify was followed by Uber in and Lyft in 2014. As in other cities around the 12 world, the disruption of this new mobility services created challenges in regulation. In September 13 2016, the government of Mexico City introduced a new tax as part of the Urban Mobility Law 14 designed to contribute to a special trust to strengthen the city's capacity to invest in sustainable 15 urban mobility called "Fondo para el taxi, la movilidad y el peatón" (fund for the taxi, mobility, 16 and the pedestrian) (SEMOVI, 2019). The tax had a direct effect on the growing supply of on-17 demand ride-hailing services in the city as it imposed TNCs a contribution of 1.5% of the fare of 18 each trip made using these services, a cost that was transferred to the user. Such a scheme is unique 19 in the LAC region, and it has relevance for this research as it bears direct implications for the 20 affordability of app-based ride-hailing compared to traditional taxis and other modes of transport. 21

In this section, we build on the literature review presented earlier in the paper to propose a 22 conceptual framework explaining the factors that can influence the adoption of TNC services in 23 urban contexts, as well as the characteristics that can distinguish ride-hailing from other transport 24 alternatives. The framework is informed by the main features of urban transport in Mexico, 25 26 although its main components reflect the main types of drivers of ride-hailing choice in the international literature. There are three starting points for the framework. First, we hypothesize 27 that ride-hailing adopters are mainly non-frequent users of the service or those that make 28 29 occasional trips during the month (Alemi et al., 2018a; Tirachini and del Río, 2019). Second, ridehailing is unaffordable for a considerable share of the population as a frequent mode of transport. 30 This point is expected to have greater relevance in contexts with higher concentration of poverty 31 32 and income inequality. And third, crime problems and risk of sexual harassment in public transportation and public spaces may increase the appeal of ride-hailing in particular times of day, 33 under specific circumstances, or for determined subgroups of the population. Mexico City (as other 34 major cities in LAC) has experienced challenges associated with high rates of crime and insecurity, 35 as well as well-documented frequent issues of harassment and gender violence in public transport 36 and public space. While aspects of crime and gender security are likely relevant for most contexts 37 where such services are in use, the idea that ride-hailing could be a mechanism to feel safer when 38 traveling could have additional relevance in Global South contexts. 39

40

Source: Own Elaboration

3 4 5

1 2

6 Additionally, our framework (Figure 1) incorporates four dimensions that have been suggested 7 by previous research to influence patterns of use of ride-hailing: i) the Built Environment, ii) Individual Mobility Demand, iii) Purchasing Power, and iv) Attitudinal Preferences. This group 8 of variables is complemented with the gender of the person and with factors affecting Personal 9 Security as one of the conceptual contributions of this article. It is also important to highlight that 10 our proposed models are heavily influenced by life stage and household composition (Janke et al., 11 2020). In Figure 1, thick lines are interpreted as having a direct effect and dashed lines as having 12 a mediated effect. For example, purchasing power and attitudinal preferences are directly affecting 13 ride-hailing adoption. Concerns about personal security can directly affect ride-hailing as well as 14 shape attitudes that ultimately influence ride-hailing. In the first case there is a thick line from 15 16 personal security to ride-hailing adoption, and in the second case there is a dashed line from 17 personal security to attitudinal preferences and late a thick line from attitudinal preferences to ride-18 hailing usage.

3.1. Built Environment

3 The built environment, which encompasses infrastructure and urban form, influences ride-4 hailing usage and patterns through several mechanisms. First, the degree of quality and coverage of public transport infrastructure and services (Alemi et al., 2018a; Dias et al., 2017; Etminani-5 Ghasrodashti and Hamidi, 2019) can influence ride-hailing usage in two ways. For high-income 6 individuals who live near public transit stations, public transportation may serve their usual trips 7 8 such as work or school, while ride-hailing may serve many of their non-usual ones, such as 9 attending social events or seeing a doctor, and to more dispersed locations or at times not well served by public transit. In areas with high levels of congestion and limited parking, combining 10 public transportation and ride-hailing services may potentially reduce car-ownership by providing 11 a flexible alternative that offers the comfort of the car when needed without the added burden 12 associated with owning it. Conversely, those living outside of mass transit hubs or in transit 13 desserts and/or for those without access to private vehicles (households that share a vehicle), ride 14 hailing may serve occasional trips not easily reach on foot or by transit. 15

Second, areas with high degrees of land use mix and density may have either downward or 16 upward effects on ride-hailing demand (Marquet, 2020). People living or working in dense mixed-17 use areas with more opportunities clustered together, might prefer walking or biking instead of 18 using TNCs for short trips, generating a downward effect. The upward effect is like that of public 19 transportation discussed before. If travelers can reach many destinations on foot or without relying 20 on owning a private vehicle, they may forgo auto ownership altogether and use ride-hailing for the 21 trips that go beyond walkable or transitable distances. In addition, among those who do own cars, 22 parking restrictions in denser mixed-use areas may induce ride-hailing amongst travelers looking 23 to save time and hassle searching for parking and to save on parking costs. Conversely, investments 24 in high quality public infrastructure can spur more mixed land used and reinforce the cycle of 25 walking or cycling for short trips and ride-hailing for longer trips. Finally, higher rates of auto-26 dependency may occur in low-density and single use zones that impose long distances between 27 origins and destinations, and an urban form that is difficult to serve efficiently through mass transit. 28 29 Although car dependent urban forms can reduce the overall demand for ride-hailing, in these environments, it may be an attractive back up to the car in many instances. 30

31

1 2

32 33

3.

34

3.2. Mobility Needs

The dimension of mobility needs encapsulates the different trips that people perform. 35 Individuals living in households with more diverse and intensive mobility needs are more likely 36 to, eventually, perform more ride-hailing trips because they cannot perform all the trips in the same 37 transport mode. For example, trips with baggage, to medical appointments, or with children are 38 not as easy to conduct in public transportation as in ride-hailing. In addition, personal mobility 39 matters, as do the needs of other members of the household. A reason for this is negotiations at the 40 household level about the distribution of budgets and access to the car (Levy, 2013a; Schwanen, 41 2011). Something that we consider a crucial element is the role of people in charge of elders or 42 kids. Ride-hailing might look like a more appealing alternative when traveling with elders or 43 children than regular public transportation. 44

45

46

1 *3.3.Attitudinal Preferences*

Preferences are expected to vary across different levels of education and age. For example, the level of engagement in technology (Fu, 2020; Kong et al., 2020), the literacy to use it, and the trend towards being an early adopter. Moreover, the use of a TNC app demands basic knowledge about technology, such as knowing how to create an account, how to make electronic payments, or how to navigate an interactive map to input trip origins and destinations. Amongst younger and highly educated individuals, this is likely common knowledge, but for older cohorts, it may present a challenge that may constrain their use of ride-hailing.

A second dimension we consider is attitudinal preferences towards the environment, which can affect ride-hailing adoption in two ways. On the one hand, individuals with pro-environment attitudes might avoid using ride-hailing services, given that the service may have similar environmental consequences to those of driving a personal vehicle. On the other, this group may avoid owning a car and make their frequent trips in more sustainable alternatives such as public transit and walking and use ride-hailing for the non-frequent trips that are not easily made in these alternatives.

17 Finally, attitudes towards different transport modes are likely to differ in Latin America compared to other contexts examined in the academic literature. Not only travelers may have 18 negative perceptions regarding the quality and or security of public transport modes derived from 19 previous experiences. In Mexico City, similarly to other contexts in LAC, the use of public 20 transport, and to some extent walking and cycling, are associated with differences in class and 21 income, and often avoided by higher-income residents (Gandelman et al., 2019; Guerra et al., 22 23 2018; Jauregui-Fung et al., 2019). In Mexico, where the backbone of the transport system is composed of Jitney-semi-informal minibus services that are characterized as low quality, non-24 reliable, and insecure (Flores-Dewey, 2019), tendencies of positive associations of car ownership 25 26 with status and power are more likely to manifest alongside an increasing use of collective transport by groups with lower purchasing power (Gallego et al., 2013). Other key issues are fear 27 of crime and sexual harassment, both of which are disproportionately experienced by women 28 29 (Dunckel-Graglia, 2013; Dunckel Graglia, 2016).

30 31

32

2

3.4.Purchasing Power

33 Ride-hailing is an expensive service relative to other transport modes in Latin American cities. Particularly in the developing country context, where high rates of inequality and poverty 34 are persistent, ride-hailing may be unaffordable for a substantial part of the population. Initial 35 proxies for purchasing power are the socioeconomic stratum of the zone where the person lives. 36 Stratum is Other important proxy is the level of education, with more educated individuals 37 expected to have higher average incomes than those with lower levels of education (Ferrevra et 38 al., 2017). Education is a variable that affects two dimensions (purchasing power and attitudinal 39 preferences) of ride-hailing use and is expected to have significant relevance in explaining ride-40 hailing. 41

Finally, car ownership has theoretical two principal influences on ride hailing. People in the right economic conditions can buy cars, which can reduce demand for ride haling but may also increase it where car usage is expensive (parking). Also, in some contexts, people with a private vehicle can have access to employment opportunities that are not available in other transport modes, which in turn increases available disposable income. 1 *3.5.Gendered Factors*

3 The variable, gender, is expected to be significant in most of the models we present later 4 in the article. At the top left of Figure 1, the square "Gendered Factors" is not a dimension itself. Instead, it is a common area of variables from the aspects discussed here that overlap with gender. 5 6 Because of the typical role that woman play related to household care related activities, their travel patterns tend to distinct from those of men (BID, 2018). Typically, women's travel is more 7 8 complex due to their tendency to oversee more of the household related shopping and typical 9 increased responsibilities related to care of children and elders. Compounding these trends, they 10 have access to lower quality and slower modes of transport and access to the private vehicle in households leans towards the working-male, leaving women with the need to look for alternative 11 modes of travel (Levy, 2013b; Schwanen, 2011). Moreover, gender-based violence deserves 12 special attention when studying the ride-hailing phenomena in Mexico City. Given the high rates 13 of crime and sexual harassment in Mexico City, as mentioned previously, the government has 14 developed strategies to increase safety and security form women, but with limited success 15 (Dunckel-Graglia, 2013; Dunckel Graglia, 2016). 16

The combination of more complex mobilities, less access to use the car in the household, and being fearful to public transport, may lead women with the economic capacity of affording ridehailing to turn to it as an alternative mode.

In summary, the models proposed for this article (see section 4 for the variables used in every model and section 5 for the results) are based on the conceptual framework presented, in order to assess the validity of hypotheses posed including 1) that gender is a key variable for the adoption of ride-hailing, 2) that younger people with high educational attainment are more likely to use ridehailing, and 3) that the built environment should explain some share of ride-hailing trips. In the models, we do not include variables expressing attitudinal preferences and subjective perceptions of fear of crime due to the lack of these variables in the survey we used for the models.

27 28

29

30

2

4. Data and methods

We use the most recent Household Transport Survey HTS in Mexico City (2017) to run 31 32 two types of categorical models of ride-hailing adoption. First, we employ a logistic regression to understand the factors influencing ride-hailing adoption, with the outcome variable being whether 33 an individual is a ride-hailing user or not (defined as performing at least one trip on a weekday or 34 weekend). Our second model is a multinomial logistic regression that measures the impacts of 35 different factors in our conceptual framework on mode choice between ride-hailing versus other 36 modes. The outcomes include a set of transport modes available in the city, with ride-hailing 37 assigned as the base outcome. In constructing our models, we draw upon the conceptual 38 framework presented in the previous section and the availability of information in the HTS. Next, 39 we present an overview of the dataset used and the mathematical logic of the models. 40

41

42 43 4.1. Household Travel Survey

The 2017 travel survey for Mexico City include 142,415 persons in 66,625 households,
living in 195 districts that encompass the metropolitan area of Mexico City, (frequently referred
to as the Valley of Mexico Metropolitan Zone ZMVM (Zona Metropolitana del Valle de México,

1 in Spanish)). Only respondents six years and older could answer the survey and provided detailed information about their trips performed the prior week for a randomly chosen weekday (Tuesday, 2

Wednesday, or Thursday) and Saturday. 3

4 For our analysis, the dataset is grouped into ride-hailing users (1,522 respondents) and non-5 users (140,893 respondents) as shown in Table 1. We define a ride-hailing user as an individual that reported at least one ride-hailing trip during the weekday or on Saturday. We construct three 6 variables to measure characteristics of the built environment of the district of residence of the 7 8 travel survey respondents, Transit Intensity, Trips within District, and Distance to Center. Transit intensity corresponds to the proportion of public transport trips (considering all public transport 9 modes) relative to all trips made within a given district (considering all modes). Trips within 10 district of residence is a measure of the total trips in the sample that originate in one district and 11 finish in the same district. Distance to the center is the distance from the centroid of each district 12 to the Central district of the zone of study (ZMVM). Transit intensity, Trips Within District and 13 Distance to Center variables are defined at the district of residence of each individual. We calculate 14 the quartiles for each of these variables. Finally, Strata is a commonly used proxy for income and 15 socio-economic levels in the Latin American context (Cantillo-García et al., 2019). The variable 16 assigns a value from 1 to 4 to assign a household's socioeconomic status building on a combination 17 of socioeconomic and housing characteristics. As an aggregate measure, it provides only an 18 approximation based on the quality of housing materials and available facilities, as well as aspects 19 of individuals in the household associated with income. Strata 1 is often associated with lower-20 21 income households and 4 corresponds to the highest socioeconomic status.

	Medium	25.21	24.44
	Medium/High	26.29	14.32
	High	26.93	9.99
Distance to Center	First Ring	23.53	46.19
	Second Ring	24.51	26.61
	Third Ring	26.01	20.63
	Fourth Ring	25.94	6.57

1

Notes: Transit Intensity quartiles: 1st quartile goes from 1.9% to 30.5%; 2nd quartiles from 30.5% to 34.5%; 3rd quartile
from 34,5% to 38.9%; and 4th quartile from 38.9% to 64%. Trips Within District quartiles are as follows: 1st quartile
includes from 1.3% to ,31.3%; 2nd quartile from 31.3% to 38.8%; 3rd quartile from 38.8% to 46.8%; and 4th quartile
from 46.8% to 85.7%. We calculate distance to center and report by quartiles, where the 1st quartile goes from 0 Km
to 1.1 km; the second quartile from 1.1 km to 16.2 km; and the 3rd quartile from 16.2 Km to 24.8 Km; and the 4th
quartile from 24.8 Km to 59.2 Km.

Table 1 presents characteristics of variables used in our models and how they relate to ridehailing adoption and intensity. Although there are more females than males in the survey, there is
a slight increase in ride-hailing users who are female (58.0%) compared to non-user females
(51.6%). In terms of age, ride-hailing users have more people between 20 and 30 years old (30.9%)
than non-users (20.3%). 48.41% of the non-users and 19.8% of users have a low level of education.

Transit intensity is relatively equally distributed among the four categories in the case of the non-users, with around 25% in each group. The case of the users is different, and it is skewed towards more presence in the Medium/High category and the High category with 31.6% and 30.4%, respectively. Trips within District and distance to the center have a similar pattern. Additional information about variables in the survey is presented in appendix A.

In the annex we include descriptive statistics for each of the modes where is possible to
observe that ride-hailing is composed mainly of door-to-door trips (trips with just one stage), with
91.69% of trips being a one-stage trip.

In Figure 2 we present the share of trips by gender according to all the purposes included in the transport household survey. The plot at the top includes all the modes whilst the plot at the bottom retains only ride-hailing trips. In general terms, males (63.12%) make more work trips than females (36.88%) when all modes are analyzed, but the proportion reverse for ride-hailing trips with males making 44.17% of the work trips and females 55.83%. This could be an indication that

- 1 ride-hailing is, at some extent, being more instrumental for women than it is for men. In both plots
- 2 it is clear that women make more health trips as well as other trips.

3

1 2

Figure 3 Distribution of trips by mode and education level

4

3

5 As mentioned before, prior literature has consistently found that higher levels of education 6 are associated with ride-hailing adoption. A similar pattern is found for Mexico City (see Figure 7 3) where 57.2% of TNCs users are highly educated, a number way above the percentage of highly educated people for all the other modes. The closest mode is car with 45.56% of car users being 8 9 highly educated. The differences with all other modes are extremely large. For example, only 16.29% of Jitney commuters and 32.08% of metros users are highly educated. The categorical 10 models presented later also show that higher levels of education are related to engaging with ride-11 12 hailing.

Household travel surveys have been used in the past to study ride-hailing. For example, 13 Dias et al., used the Puget Sound Regional Travel Study (Dias et al., 2017) and Jiao et al., used the 14 National Household Travel Survey (NHTS) from the United States (Jiao et al., 2020). In Toronto, 15 16 a study (Young et al., 2020) combined the 2016 Transportation Tomorrow Survey TTS with OpenTripPlanner and GTFS to simulate travel times in different transport modes and make 17 comparisons with simulated ride-hailing trips. Also in Canada, another study (Habib, 2019) used 18 the TTS to investigate competition between Uber and other transport modes in the Greater Toronto 19 20 and Hamilton Areas.

- 22

23

4.2. Categorical Models

Turning to the modeling framework, the first model employed is at the individual level and is a binary logistic regression where the outcome variable is one if the person is a ride-hailing user 1 (as specified for Table 1) and zero otherwise. Mathematically, the logistic model has the following2 form,

- 3
- з 4

 $logit(\pi(x)) = log\left[\frac{\pi(x)}{1-\pi(x)}\right] = \alpha + \beta * x \quad (1)$ $\pi(x) = \frac{e^{\alpha + \beta * x}}{1+e^{\alpha + \beta * x}} \quad (2)$

- 5
- 6

7 where $logit(\pi(x))$ is the link function, α the intercept parameter, β a collection of 8 estimated parameters and x is a vector of covariates including built environment and demographic 9 variables, as discussed above.

The logistic model includes all variables in Table 1 plus occupation, relationship with the head of household, vehicles in the households, number of children and elders in the household. Other variables included to capture the complex mobility of each person were, i) percentage of trips per different purposes (considering the weekday trips and the Saturday trips), ii) percentage of trips at night, iii) total trips made by the entire household in a weekday, and iv) trips made by the household on Saturday.

16 The second model, the multinomial, is a generalization of the logit model that allows the outcome variable to have more than two categories. For our case, the outcome variable is the 17 primary mode used for each trip performed by the respondent, where in the case of car the traveler 18 could have either traveled as a passenger or as a driver. The multinomial model has a similar 19 20 specification to the one used for the logistic model, though there is a significant change. Since the unit of analysis is at the trip level, we included the built environment variables by origin and 21 22 destination. We include for example, Transit Intensity for the District where the person lives but also the Transit Intensity of the trip where the specific journey started and the Transit Intensity for 23 the District where that same trip ends. Moreover, we included travel time of each trip and an 24 25 interaction between gender and elders in the household.

5. Results

27 28 29

26

5.1. Ride-hailing adopters vs. Non-Adopters

30 The results for the logistic model of ride-hailing adoption is presented in Table 2. Several 31 demographic variables are important determinants of ride-hailing adoption. As expected and 32 discussed in the conceptual framework, gender is a significant variable, with the odds ratio of 33 34 making ride-hailing trips increasing by 34.9% if the traveler is a female (with reference to male). This finding (an others from the multinomial model presented below) is different from standard 35 literature that has suggested that gender is not important or that males are more likely to engage in 36 ride-hailing. We think that this difference constitutes the main particularities of the ride-hailing 37 38 phenomena in Mexico City.

For the age variable, we assigned the category between 20 and 30 years old as the reference category. As age increases, the magnitudes of the estimates reduce. This suggests that older generations are least likely to adopt ride-hailing services and is similar to findings in international literature. Interestingly, the age cohort between 10 and 15 years old increases the likelihood of adopting ride-hailing services (odd ratio equals to 1.375). This could be an effect of parents relying in TNCs to guarantee mobilities for their children.

1

2 As many previews studies in developed countries have highlighted, education is also one of the more influential variables on ride-hailing adoption in Mexico City. Compared to less 3 educated individuals, those with more education are significantly more likely to adopt ride-hailing, 4 with an estimated increase of 66.5% (statistically significant at the 1% level) in using ride-hailing 5 for medium educated users and by 241% (statistically significant at the 1% level) for high educated 6 users. The coefficient for the number of trips a person performs suggests that for an additional trip 7 in a weekday, the odds ratio of using ride-hailing against not using it grows by 6.6%, but for extra 8 trips on a Saturday, the growth is substantially more (of 23.5%). It is important to note that there 9 could be an endogenous relationship here in which the availability of ride-hailing could increase 10 11 the demand for mobility or meet latent demand.

In terms of trip purpose, the percent of household trips to return home or to study is statistically less likely to be made in ride-hailing. Tours with the purpose of study, work, or come back home are considered regular trips. On the other hand, leisure, and health tips, as well as trips at night, are connected to less frequent trips or random trips. This group of variables has a positive effect on ride-hailing use, a finding also connected to previews literature and reflecting that ridehailing is instrumental for not usual trips

Also in line with international literature, the highest stratum is one of the main variables explaining ride-hailing adoption. Stratum 4, when compared to Stratum 1, has an effect of 3.805.

Transit intensity in the district of residence does not have any effect on ride-hailing use in the week prior. However, the estimates for distance to center and trips within district variables suggest that living closer to the center increases the probability of ride-hailing adoption. People
living in districts far away from the city's historical center are less likely to use ride-hailing.
Relative to the first ring, those living in the second ring, are estimated to have an odds ratio of
85.2% and among those living in the fourth ring the odds decrease to 31.7%.

5 We tested additional models adding interactions between gender and other key variables 6 such as number of children in the household, elders in the household, stratum, and education level. 7 Nevertheless, results were not significant, and all the other estimates remained similar indicating 8 that gender impacts on ride hailing may be mediated through more complex factors such as quality 9 and coverage of public transit or other available modes, built environment, and perceptions of 10 security and vulnerability.

11 12

13

5.2.Ride-hailing vs. other modes

In Table 3 we present the results of the multinomial model estimation. For brevity, we present a reduced version of the full output, including mostly the main, statistically significant results. In the appendix C we show the full version of the output. Recall that for this model the outcome variable is the individual level primary mode for a given trip.

Results for gender are not significant for Jitney, BRT, and Walking. Only for the case of 18 Taxi being a female reduces the probability of ride-hailing (odds ratio of 1.3), in all the other 19 modes the estimate is significant and towards the opposite direction. For Metro and Bus gender 20 has the higher effects on increasing the likelihood of ride-hailing: 78.4% for Metro and 89.9% for 21 Bus if the person is a female. Car has and odds ratio of 55.3% while Cycling and Moto show the 22 23 lower effect with 0.208 and 0.222, respectively. These results complement findings from the logit model and provide more evidence that, in contrast to standard understanding of ride-hailing, 24 gender is an important determinant in the Mexican context. 25

The interaction between gender and number of elders in the household show heterogeneous results across modes, but it enables a deeper look at how ride-haling is relevant for mobility of women. With the coefficient for car being the only not significant, all the other coefficients show high impacts in favor of ride-hailing. The lower odds ratio is for cycling (0.499). Al the other odds ratios are around 0.8. These results are suggesting that ride-hailing is being instrumental for the care mobilities of women. In other words, women are probably more responsible of taking care of elders in the household, and ride-hailing is a transport alternative that fits that need.

Like results found in the logistic regressions, younger generations are more likely to use 33 TNCs compared to any other transport mode. The age group between 10- and 15-years old is less 34 likely to use Jitney, Metro, BRT, Bus, Cycling, and Moto. The only mode that is more likely to be 35 used than ride-hailing in this cohort is Car. The age cohort between 15- and 20-year-old have a 36 similar pattern but higher odds ratio; moreover, estimate for BRT and car are not significant. These 37 results suggest that younger generations are already showing more positive perceptions towards 38 ride-hailing. Another interpretation is that parents are using TNCs to provide mobilities (mainly 39 for the 10- to 15-years old cohort) in a perceived safer environment where their children's location 40 can be tracked via apps. 41

In contrast, older cohorts are more likely than younger ones to prefer modes other than ride-hailing. All else equal, if a person is in their thirties, forties, or fifties (using the cohort between 20 and 30 years as the reference category), then the use of any transport mode other than TNCs is the most likely outcome, with motorcycle being the only exception. For example, for people between 50 and 60 years old, the odds ratio of using Metro over TNCs increases by 1.888. Interestingly, the motorcycle is the only mode where these patterns reverse, showing that users in
the 40- to 50-year-old group and the 50- to 60-year-old group reduce the odds ratio of using moto
by 84.5% and 63.7%. This output may be associated to risk perceptions and not with a preference
for ride-hailing.

5 For those occupied as a househusband/housewife (relative to employed outside the home), 6 the relative odds of using public transport modes (Metro, BRT, Bus) and private vehicles (car and 7 motorcycle), instead of ride-hailing decreases but increases for the case of walking (1.560 odds 8 ratio). As expected, unemployed individuals that are active job seekers are very reluctant to use 9 ride-hailing and they are more likely to use public transportation or walking. The category "cannot 10 work for life" (than can be associated with disabilities) decreases the odds ratio of using Jitneys, Metro, or Bicycle relative to ride-hailing (compared to those who are employed), indicating a 11 preference for ride-hailing among this group (see appendix). The estimates of the effect of 12 education on ride-hailing behave similarly to those for the logit model. Using the low-level of 13 education category as the reference, the two categories -medium and high levels of education -are 14 greater than one and statistically significant across all the modes, suggesting a preference for ride-15 hailing over other all the other modes amongst those with higher levels of education. 16

The coefficients for trip purposes (work trips as reference) show that ride-hailing is 17 preferred over virtually any other mode for health and leisure trips. The relationship with the head 18 of household also has an influence on mode choice. Those who reported being the partner of the 19 household head were more likely (compared to the household head) to choose walking (15.4% 20 more) instead of ride-hailing. This suggests that partners of the head of household have more 21 mobility needs that are reachable without the need of ride-hailing services or they are less likely 22 to have access to a vehicle in the household. For the categories of Son/Daughter and 23 Grandson/Granddaughter, all the other modes are favored (with the car being the only exception) 24 above ride-hailing. 25

The individual activity variables show that increased trip activity on a Saturday slightly increases the odds ratios of car (1.153) and motorcycles (1.175). The estimate for taxis is showing a positive effect (1.139). One more trip on a weekday has a similar impact, but the estimate is also significant for Jitney, Bus, and Walking. Also, the night trips variable has odds ratio estimates between 0.294 (Cycling) and 0.751 (Car).

The effect of socioeconomic strata on ride-hailing in this set of results do not appear to be 31 32 as salient as in the logistic model results (see appendix). However, relative to the lower socioeconomic strata (strata 1), individuals in Stratum 4, the highest strata, are much more likely 33 to use ride-hailing over Jitney, Metro, BRT, Walking, Cycling, and Moto. In terms of private 34 vehicle ownership, however, the impact of having one more private vehicle (car or motorcycle) 35 decreases the odds ratio of using any other mode in the model. For example, the estimate for 36 motorcycle is 0.508 in Jitneys and 0.624 in metro, meaning that those with private vehicles in their 37 households are less likely to use either a Jitney or the metro over ride-hailing for their trips. As 38 expected, the number of cars and motorcycles in the household increases the probability of trips 39 (relative to ride-hailing) made in those modes, with estimates of 3.480 and 13.523, for car and 40 motorcycle, respectively. 41

Now we move to the interpretation of the built environment variables (see appendix). In the multinomial model there are two important conceptual changes. The model does not only make specific comparisons of ride-hailing trips with trips from other modes, as the data is at the trip level the model includes the built environment variables for the origin and destination of the trip and therefore, but a more detailed view on the urban form impacts can also be found. This is the case of the transit intensity variable that does not seem to be relevant in the full logistic model, but that brings additional results in the multinomial. High Transit Intensity in the origin or destination of the trip increase the odds ratio of using public transportation above ride-hailing. For the origins, the High intensity category estimates are 1.455 for Jitney, 2.328 for Metro, 1.431 for BRT and 1.419 for Bus, and for the destination, Jitney (1.381), Metro (2.108), and BRT (1.283). The results are similar for the transit intensity in the destination (except for bus that is not significant). In conclusion, better levels of public transport provision are associated with less TNC trips.

8 The trips within district variable (that can be considered as a proxy to land-use diversity 9 and/or population density) shows a pattern of increasing usage of jitney and buses (compared to TNCs) in zones with medium and high trip intensity categories relative to low trip intensity zones, 10 but decreasing use of walking, cycling and taxi relative to TNC trips. When analyzing the 11 characteristics of origin and destination of the trips, we can observe a different pattern. For 12 example, if a person lives in a medium/high or high trip-within-district area then the estimates of 13 the odds of using public transit instead of ride-hailing increases. For example, in the case of metro 14 (versus ride-hailing), the relative propensity increases to 12.823 and 8.662, respectively. But if the 15 trip starts in a medium/high or high trip intensity district the odds for metro decrease to 0.408 16 (medium/high) and 0.524 (high) and the odds of walking or cycling increase. If the trips end in a 17 medium or high trip intensity destination the odds are similar, 0.403 and 0.527, respectively. 18

Lastly, people living further away from the city center have a higher likelihood of using Jitney compared to ride-hailing. For the case of BRT, living in the second and third rings increases the likelihood of using ride-hailing by 59% and 59.2% (respectively), though the odds ratio are in favor of BRT in the fourth ring (78.4%). If the trip starts or finishes beyond the first ring, the direction of the odds ratio leans towards Jitney.

6. Conclusions and policy implications

5 This research used two categorical models to explore how the built environment, individual 6 variables, and trip characteristics influence ride-hailing adoption and the propensity of ride-hailing usage relative other transport alternatives. The rationale of the models builds on the conceptual 7 8 framework presented in Figure 1, which incorporates the Built Environment, Individual Mobility 9 Demand, Purchasing Power, and Attitudinal Preferences, as relevant dimensions influencing ridehailing use. The framework puts special attention to gender and factors affecting Personal Security 10 as considerations previously ignored in earlier research, even though given the nature of data used 11 in the models we were not able to include variables connected to Personal Security. Our paper set 12 out to test the applicability and relevance of previously identified factors influencing ride-hailing 13 adoption in contexts outside of Latin America and Mexico. As such, findings from the previous 14 section can be divided in those confirming results in previous research and those that suggest 15 context-specific contributions to current academic debates. 16

On the one hand, our findings confirm that higher education and income have a positive 17 effect on ride-hailing adoption, and that younger users are more likely to adopt TNC services. Such 18 findings are well-aligned with existing research on ride-hailing in the academic literature (Alemi 19 et al., 2018b; Dias et al., 2017; Tirachini, 2019). Our models support the hypothesis that ride-20 hailing adopters tend to be in their twenties and that the highest levels of education are associated 21 with ride-hailing trips in Mexico City. In this context, wealthier populations who are more 22 comfortable with new technologies, marking a divide between users and non-users along 23 24 socioeconomic and demographic lines. We also found that ride-hailing is, at the time of the data collection (2017), a transport alternative to perform non-usual trips. This is reflected in the high 25 estimates found in the logistic model for leisure and health trips with 3.808 and 9.908, respectively, 26 27 which stands in contrasts with home trips (0.514), work trips (0.924 and non-significant), and study trips (0.560). 28

29 Built environment and public transit supply variables were also relevant to ride-hailing usage. The propensity to choose ride-hailing relative to other available modes decreases where 30 there is a high level of transit supply. We also observe that areas characterized as having a higher 31 degree of land-use diversity and population density, as measured by trip intensity, have higher 32 levels of public transit usage However, in these zones, TNCs are preferred over walking and 33 cycling. In addition, individuals living further away from the city center have a higher likelihood 34 of using public transportation compared to ride-hailing, perhaps due to the longer distances and 35 costs in ride-hailing that would be involved in trips in lower density areas of the city. 36

On the other hand, results about gendered factors deviate from what the international 37 literature on ride-hailing suggests, pointing at gender and the influence of mobilities of care for 38 the adoption and intensity of use of TNC services as relevant factors in contexts such as Mexico. 39 40 As shown in section 2.2, research in LAC has pointed at gender as a significant determinant of travel patterns in cities in the region, with aspects associated with security, violence and crime 41 42 affecting this group more visibly than others. Furthermore, emerging literature on mobilities of care support the hypothesis that gender (being female) is a relevant variable in ride-hailing 43 adoption as tested in the logistic model. We find that women are 35% more likely to use ride-44 hailing modes compared to men. This result was also confirmed in the multinomial model 45 46 comparing the relative odds of choosing other modes relative to ride-hailing for trips reporting in the reference week. Women were found to prefer ride-hailing to all other modes except for 47

walking, where we did not find a significant effect. Moreover, cycling (relative to ride-hailing)
had the lowest odds ratio estimate (0.183) for women. This finding is reinforced by the
"househusband/housewife" category (occupation) that shows significant values and estimates in
favor of ride-hailing relative to most alternative transport modes analyzed. The only exceptions
were walking (estimate in the other direction) and cycling (not significant).

6 Findings related to gender suggest that individual motorized modes and taxis currently 7 meet some of the complexities associated with the needs, perceptions, and vulnerabilities of 8 women when moving in the city in different forms of transport. International literature on women's 9 travel consistently demonstrates that women are more likely to trip chain, carry packages and 10 accompany others during their trips, and make more stops and yet are less likely to have access to a private vehicle even if there is one in their household. In the Latam context they also experience 11 high rates of harassment or fear of harassment in public transit, limiting times of day and contexts 12 that they feel safe traveling in this mode. It is not surprising that women who can afford to access 13 ride-hailing, a form of transport that offers flexibility for door to door on demand trips, similar to 14 that of a car and security features, prefer it over other modes. Security may be one of the main 15 drivers for the high ratios observed in such modes for women. This suggests a potential for TNCs 16 to adjust their operation and service patterns for women to increase perceptions of safety 17 concerning other modes. They also point at preference in this group for individualized travel 18 options under specific, non-usual, circumstances, which can open spaces for integration with 19 public transit in areas and times of the day perceived as less safe. 20

The methodology followed in this paper shed light on the main characteristics affecting 21 ride-hailing adoption as well as to establish some differences with other transport alternatives. 22 Nevertheless, there are some limitations that should be addressed in further research and that are 23 based mainly on the nature of the information used for the analysis: the Mexico City transport 24 household survey from 2017. This study is limited by the fact that at the time of the survey, ride-25 hailing as a service was still consolidating and had much less diversification of services and market 26 segmentation that is now being observed. Moreover, a transport household survey is an instrument 27 used to understand commute patterns, but it is not specifically designed to study ride-hailing. As 28 29 consequence, some key variables are not currently being considered. For example, it would be important to ask the mode commuters would have used should ride-hailing not being available for 30 their last ride-hailing trip. As mentioned in the introduction, literature review and conceptual 31 framework, the level of engagement with technology is a key factor in explaining ride-hailing 32 usage. Future studies should find mechanisms to measure engagement with technology as well as 33 other subjective variables reflecting perceptions of ride-hailing services. 34

Although we present a multinomial model, we did not move to a more elaborated discrete choice model such as mixed model or nested model given database limitations; namely reported trips in the survey, do not include set of scenarios where respondents are asked to select an option for a particular trip among different alternatives with different modes, costs, travel times, and other characteristics (as is the case in a discrete choice experiment). Further research in Mexico City could incorporate a discrete choice experiment and even evaluate integration with public transit.

A future line of research should focus on completely unpacking the connection between gender and ride-hailing. The coefficient estimates for gender in the logit and multinomial models shows an association, however we tested multiple interactions of gender with key variables (like stratum, education, household composition and trips purposes) without obtaining any statistically significant results, leaving the underlying mechanism of the effect unknown.

1 Challenges for policy concerning ride-hailing in contexts like Mexico are associated with 2 the tension between opening spaces for modern travel alternatives that may serve a small portion of the demand and reducing transport-driven inequalities across the population. Findings in this 3 4 paper point at potential entry points for the exploration of co-produced solutions between regulators, TNC providers, users, and incumbent operators in other modes. The infrequent nature 5 6 of trips served by ride-hailing suggests a potential for multi-modality and changes in pricing and 7 operation schemes that can better respond to the needs of the more vulnerable users. Positioning 8 ride-hailing as a viable substitute for the private car and motorcycle can potentially contribute to reducing car dependency before reaching saturation levels. 9 10 Our models did not include attitudinal variables. However, we acknowledge that they can

11 shed light on some of the issues. With the purpose of foster a more comprehensive research agenda 12 in ride-hailing, we believe that future research should include this dimension and build on specific 13 survey instruments that ask for peoples' perceptions such as fear of crime.

Notes: Multinomial Model. Odds ratio, reduced version. For complete version see the appendix. P values were calculated with original estimates. *** p<0.01, ** p<0.05, * <0.1. Standard errors in parentheses.

Chi Square for the full model: 498936.31***. Pseudo R2 for the full model: 0.34.

Author Statement

Below we outline individual contributions according to CRediT roles.

Orlando Sabogal: Data curation; Formal analysis; Investigation; Methodology; Software; Validation; Visualization; Writing - original draft; Writing - review & editing.

Daniel Oviedo: Conceptualization; Formal analysis; Investigation; Methodology; Project administration; Resources; Supervision; Validation; Writing - original draft; Writing - review & editing.

Lynn Scholl: Conceptualization; Formal analysis; Funding acquisition; Investigation; Methodology; Project administration; Resources; Supervision; Validation; Writing - original draft; Writing - review & editing.

Amado Crotte: Conceptualization; Formal analysis; Funding acquisition; Investigation; Resources; Supervision; Validation.

Felipe Bedoya: Data curation; Formal analysis; Investigation; Validation; Visualization.
