The Editor-in-chief

BIOTROPICA

Dear Editor,

Submission of Revision: Manuscript ID BITR-21-303 entitled “Roosting behavior and roost selection by *Epomophorus gambianus* (Pteropodidae) in a West African rural landscape”

We wish to express our appreciation for the consideration of our manuscript, and giving us

the opportunity once again to resubmit a revised version of this manuscript. We appreciate the time and effort that you, the subject editor and the reviewers dedicated to providing feedback helpful comments on our manuscript and are grateful for the valuable comments on and improvements to the manuscript.

In this revised version, we have addressed all reviewers' comments, and issued raised by the reviewers. Please see below, for a point-by-point response to the Reviewers' comments. Responses to reviewer comments are in *italics*. All line numbers refer to the revised manuscript file.

4 Subject Editor

5 Thank-you for your thorough revision of the manuscript. Both reviewers are happy
6 with the new version and the comments made by them are very minor. One of the
7 issues raised by Reviewer 2 involved clarity of the terms related to roosting trees,
8 and so I thought you should have the chance to check this comment and consider
9 changing the terms to ensure there is no confusion for the readers.
10
11
12
13

15
16 *Thank you very much for your comment and for the chance to respond to issues*
17 *raised once again.*
18
19
20
21
22

23 I also found an error on L72: I assume pubs should be pups.

24
25 *Thank you for picking up this error. "Pubs", corrected to "pups" (Line 72).*
26
27
28
29
30

31 **Reviewer 1**

32
33 Dear authors,

34
35 Thank you for the polite and detailed response to my comments. I am very happy to
36 see this come out and look forward to spreading it among interested readers.
37
38

39 Well done.
40

41
42 *Thank you for your kind words and also for your initial comments in the first review*
43 *which we agree have helped improve the manuscript.*

47
48
49

50 *Reviewer 2*

51 The changes made to this revision of the manuscript have addressed my concerns
52 from the first review. I have only a couple of very minor wording suggestions for
53 clarity. See attached. Congratulations on this important contribution to the fruit bat
54 research literature.

6 *suggestions and comments provided in this revision and believe these will help*
7 *improve the manuscript.*

11 Edits:

12 Line 124 Capitalize "Old World"

13 *"old world" capitalised to "Old World" as suggested. (Line 124)*

14 Lines 246-256 Apologies for complicating the idea of avoidance in my previous
15 reviewer

16 comments. I recognize that Preferred vs. Avoided are the common terms in this type
17 of

18 analysis, and I hope my concerns about "avoided" trees actually being used did not
19 confuse the revision of this part of the study. I think the use of "less preferred" might
20 work, although

21 preferred still suggests some selectivity for these trees, when in fact, these trees are
22 less

23 chosen than even the "random" trees. I do not have an alternate term to suggest, but
24 I do think it should be made clear that trees are used relative to their availability in
25 this order: preferred, random, or "less preferred". Hope that makes sense. Other
26 terms that might work for "less preferred" are: 1) infrequently selected, 2) selected
27 against if the authors would like to consider a different term that excludes the word
28 "preferred"

29

40
41
42
43
44
45
46
47 *Thank you again for the concerns raised particularly on clarifying the terms "less*
48 *preferred". To further reduce any confusion that may arise to the readers, we have*
49 *adopted the suggested term "infrequently selected" to replace the term "less*
50 *preferred". (Line 246-257). We have also modified line 247-248 to show that use of*
51 *tree speies relative to their availability was in the order: preferred, random, or*
52 *infrequently selected.*

1
2
3
4 *Subsequently all use of the term "less preferred" pertaining to selection by E.*
5 *gambianus has been replaced by "infrequently selected" in the manuscript. (Lines*
6 *427, 501, table 2)*
7
8
9

10 Line 289 remove "only" (40 of 60 bats being redetected is actually pretty high)
11
12

13
14 *Agreed. "only" deleted (Line 290)*

5
6 18

7
8 19 Urbanization is driving many species to inhabit modified landscapes, but our understanding
9
10 20 of how species respond to this remains limited. Bats are particularly vulnerable due to their
11
12 21 life-history traits but have received little attention. We describe the roosting behavior and
13
14 22 roost site selection, including maternity roosts, for the Gambian epauletted fruit bat
15
16 23 (*Epomophorus gambianus*) within a modified forest-savannah transition ecological zone in
17
18 24 Ghana, West Africa. We compared characteristics of roost and non-roost sites to test the
19
20 25 hypotheses that roost site selection is non-random and that maternity roost site selection
21
22 26 differs from non-maternity roosts. Male bats were more likely to switch roost (mean= $0.49 \pm$
23
24 27 0.23 bat days, $N=23$) than females (mean= 0.33 ± 0.18 bat days, $N=7$) while linear distances
25
26 28 between roosts used by males (255 ± 254 m) were significantly longer than for females (102
27
28 29 ± 71 m) ($t = 4.50$, $df=86$, $P < 0.0001$). Roost trees were more likely than non-roost trees to be
29
30 30 bigger, taller, occur closer to buildings, and be in relatively open and less mature plots;
31
32 31 maintaining such trees in modified landscapes could benefit the species. Lactating bats
33
34 32 selected a subset of roost trees but significantly, those that contained a greater number of
35
36 33 bats, a strategy which may reflect predator avoidance, or other social co-operation benefits.
37
38 34 Although there was a preference for five tree species, other trees with preferred
39
40 35 characteristics were also used. Our findings contribute to the understanding of how species
41
42 36 utilize modified landscapes, which is important in the management of biodiversity in the
43
44 37 Anthropocene.

10 44 **1. INTRODUCTION**

11
12 45 The majority of all terrestrial ecosystems have been modified by humans and this has resulted
13
14 46 in an increasing number of species being driven to inhabit human modified landscapes
15
16 47 (Galán-Acedo et al., 2019). Bats are particularly susceptible to anthropogenic changes
17
18 48 because of their low reproductive rate, longevity, and high metabolic rates (Voigt &
19
20 49 Kingston, 2016). Our understanding of how wildlife, including bats, respond to urbanization
21
22 50 remains limited (Barclay et al., 2003). Unfortunately, the lack of information about the
23
24 51 ecology of many bat species compounds this, making it difficult to assess potential threats or
25
26 52 the implementation of suitable mitigation measures. The paucity of information on bat
27
28 53 ecology is often attributed to the difficulty in conducting ecological studies on bats because
29
30 54 of their nocturnal behavior (Limpert et al., 2007). Although advancements in telemetry have
31
32 55 helped to gain insight into habitat use and movements by bats (Kalcounis-Rüppell et al.,
33
34 56 2005; Mildenstein et al., 2005), many species disperse over very long distances making it
35
36 57 difficult to track them. Flight also imposes constraints on the weight of tracking devices that
37
38 58 bats can carry; although recent and future improvements in tag miniaturization should
39
40 59 increase our ability to study their ecology.
41
42
43
44
45

46
47 60 Tree roosting bats are particularly vulnerable to habitat modification which presents a
48
49 61 two-sided problem; the loss of roosting sites and the loss of suitable foraging habitat (Hayes
50
51 62 & Loeb, 2007). Because roosts play vital roles in fitness and reproductive success (Kunz &
52
53 63 Lumsden, 2003; Vonhof & Barclay, 1996), factors that affect roosts can have significant
54
55 64 effects on the overall survival of bats. By selecting an optimum roosting site, bats achieve
56
57 65 better protection from adverse weather conditions and predators, enhanced chances of
58
59
60

1
2
3 66 successful mating and maternal care, increased social interactions and reduced energetic costs
4
5 67 in commuting to foraging sites (Kunz, 1982; Kunz & Lumsden, 2003; Neuweiler, 2000; Tan
6
7 68 et al., 1999). These benefits can be compromised if land use-changes and or other habitat
8
9 69 modifications cause bats to select suboptimal roost sites.
10
11

12 70 Within the general study of habitat selection, roost site selection is particularly
13
14 71 important to understand because roosting sites are susceptible to large scale disturbance and
15
16 72 mortality events (O'Shea et al., 2016) where mothers and pups may be particularly
17
18 73 vulnerable. Understanding roost selection in bats is vital to the successful management and
19
20 74 conservation of bats, especially in modified landscapes. Available information on roost
21
22 75 selection by bats shows a strong research bias towards cavity-roosting temperate-zone species
23
24 76 (e.g. see Kalcounis-Rüppell et al., 2005; Lacki & Baker, 2003) for which roost selection
25
26 77 pressures may differ from tropical tree-roosting species. For instance, temperature as a
27
28 78 selection pressure may be more pronounced for cavity-roosting temperate-zone bat species
29
30 79 (Willis & Brigham, 2005) but may not be as vital to tropical species where temperatures are
31
32 80 relatively warmer and more stable throughout the year. For tropical species, roosting behavior
33
34 81 may be more generally influenced by predators (Lima & O'Keefe, 2013).
35
36
37
38
39

40 82 Roost selection often depends on the characteristics of the structure being utilized,
41
42 83 such as availability, physical structure and reliability (Kunz & Lumsden, 2003). Because
43
44 84 factors that determine how resources are used by animals may vary depending on scale
45
46 85 (Manly et al., 1993), roost selection is best studied at multiple spatial scales. Studies
47
48 86 investigating selection, typically, have examined characteristics for selection at the tree-level,
49
50 87 plot/stand level and landscape-level (e.g. Limpert et al., 2007; Lucas et al., 2015). Roost
51
52 88 selection in bats is usually non-random, and bats require specific characteristics to suit their
53
54 89 needs. Among tree roosting species for instance, taller trees with larger trunks are usually
55
56 90 selected as roosts e.g., Indian flying fox *Pteropus giganteus* (Hahn et al., 2014), large flying-
57
58
59
60

1
2
3 91 fox *P. vampyrus natunae* (Gumal, 2004), Rafinesque's big-eared bat *Corynorhinus*
4
5 92 *rafinesquii* (Lucas et al., 2015) and several *Myotis* species (Kalcounis-Rüppell et al., 2005).
6
7
8 93 Larger trees provide room to accommodate more bats in a single tree, which is a trait likely to
9
10 94 be favored by gregarious species (Gumal, 2004). Larger and taller trees might also provide
11
12 95 height for easier take-off into flight (Pierson & Rainey, 1992) and can reduce the chances of
13
14 96 disturbance or predation, especially by ground-dwelling predators (Kunz, 1982; Lumsden &
15
16 97 Bennett, 2006).

17
18
19 98 Similarly, in tree cavity roosting bats, taller and larger trees are often selected because
20
21 99 they tend to be old enough to have developed suitable cavities for roosting (Sedgeley &
22
23 100 O'Donnell, 1999, 2004), and they provide better insulation (Sedgeley, 2001). These features
24
25 101 (larger size, greater height and bigger crowns) are characteristics of older trees which have
26
27 102 relatively stronger branches that are less likely to break under the weight of a large number of
28
29 103 bats compared to younger trees. Alternatively, the preference for older trees as roosts could
30
31 104 arise from consistent usage over time of trees that have provided good conditions for
32
33 105 roosting. Such roosts, therefore, could be selected because of historical philopatry and may be
34
35 106 important in the maintenance and persistence of the colony. Specific tree species might be
36
37 107 preferred (Vonhof & Barclay, 1996) because their morphology and other characteristics meet
38
39 108 requirements for roosting space and for suitable protection through concealment.

40
41
42 109 Aside from the physical characteristics of roost trees, factors such as reproductive
43
44 110 status, predator avoidance, and physiological demands can also influence roost selection and
45
46 111 roosting behavior in bats (Kerth, 2008; Kunz & Lumsden, 2003). Conditions and
47
48 112 requirements for maternity roosts, for example, often differ from those of regular roosts
49
50 113 (Kunz & Lumsden, 2003) and may be more inclined towards minimizing energetic
51
52 114 expenditures and maximizing the survival and growth of pups (Sedgeley, 2001), thereby
53
54 115 influencing the choice of roost sites. Predator avoidance or disturbance, microclimate
55
56
57
58
59
60

1
2
3 116 requirements, or changes in distance to feeding sites can cause bats to elicit roosting
4
5 117 behaviors such as roost switching (Kunz & Lumsden, 2003; Lewis, 1995; Russo et al., 2005).
6
7
8 118 This is usually common in foliage roosting bats which exhibit roosting fidelity to roosting
9
10 119 range with several trees, rather than to a single tree (Kunz, 1982; Vonhof & Barclay, 1996).

11
12 120 The Gambian epauletted fruit bat (*Epomophorus gambianus*) is widespread and very
13
14 121 common in West Africa. This species occurs in, and utilizes, a wide variety of natural
15
16 122 habitats such as savannah woodlands and forest-savannah mosaics but also is commonly
17
18 123 recorded in anthropogenically modified landscapes. Like most Old World fruit bats
19
20 124 (Pteropodidae), this species plays important roles in the ecosystems in which it occurs,
21
22 125 contributing to vital ecosystem services, such as pollination and seed dispersal (Amponsah-
23
24 126 Mensah et al., 2019; Kunz et al., 2011). The species roosts singly or in loose colonies in
25
26 127 foliage by hanging freely from branches in trees (Boulay & Robbins, 1989; Happold, 2013).
27
28 128 As for other species, such as the straw-coloured fruit bat (*Eidolon helvum*), Pohle's fruit bat
29
30 129 *Scotonycteris Ophiodon*, and the Hammer-headed fruit bat (*Hypsignathus monstrosus*), the
31
32 130 loss of suitable habitats for both feeding and roosting has been identified as a threat to this
33
34 131 species, resulting in range-wide declines (IUCN, 2021; Mickleburgh et al., 2002).

35
36
37
38 132 In this study, we describe roosting behavior and the roost site selection for both
39
40 133 maternity and non-maternity roosts used by *E. gambianus* within a modified rural landscape
41
42 134 in the forest-savannah transition ecological zone of Ghana, West Africa. We test the
43
44 135 hypothesis that roost site selection by *E. gambianus* is non-random and predict that, similar
45
46 136 to observations in other pteropod species, this species selects specific characteristics (such as
47
48 137 bigger and taller trees) that differentiate roost sites from non-roost sites. We also test the
49
50 138 hypothesis that maternity roost site selection differs from that for non-maternity roosts. Since
51
52 139 the species is not known to form single-sex maternity colonies, we predict that nursing bats
53
54 140 utilize a subset of available roosting sites, especially those that offer increased protection for
55
56
57
58
59
60

1
2
3 141 pups. To test these predictions, we compare tree level, plot and landscape level characteristics
4
5 142 of roost trees vs non-roost trees and also for maternity vs non-maternity roosts. By
6
7 143 radiotracking bats, we also provide descriptions of roosting behavior of this species and
8
9 144 predict that patterns of roost use by nursing female bats differs from those of males due to the
10
11 145 energetic constraints associated with reproduction in females.
12
13
14
15 146

17 147 2. METHODS

21 149 2.1 Study site

23 150 Data for this study were collected in Ve-Golokuati, a town located in the Volta region of
24
25 151 Ghana (6° 59' 55''N, 0° 26' 18''E). This rural town occurs within the wet semi-equatorial
26
27 152 climatic zone with rainfall occurring in a double maxima pattern (annual range 1,016–1,210
28
29 153 mm). The vegetation is heterogeneous with areas of regenerating secondary forest, farm bush
30
31 154 and remnant pockets of the original forest which is a transition between semi-deciduous
32
33 155 forest and Guinea savannah woodland forest. Changes to the original forest are mainly due to
34
35 156 agricultural use, timber exploitation, and the expansion of human settlements within the area.
36
37 157 A population of about 5,000 *E. gambianus* that roosts within several trees in the town
38
39 158 (hereafter referred to as a colony) was the focus of this study. The extent of this colony (82.6
40
41 159 ha) was used to define the limits of the study area for the data collection.
42
43
44
45

47 160 2.2 Locating roost trees

48
49 161 For this study, we classify a roost as a tree within which bats were roosting. Trees within the
50
51 162 study area were searched for the presence of roosting *E. gambianus* bats. Roosting bats were
52
53 163 also located using radio-telemetry. Bat trapping for radio tagging was done using ground mist
54
55 164 nets (3-5 m high above ground level, 6-18 m long) between 1800 h and 0600 h during
56
57 165 trapping nights. All bat trapping and handling techniques followed the guidelines of the
58
59
60

1
2
3 166 American Society of Mammalogists (Sikes et al., 2011). Radio tags weighed between 5.0 g
4
5 167 and 6.3 g (mean 5.7 ± 0.3 g) and bats that were fitted with radio-tags weighed between 82 g
6
7 168 to 150 g (mean 113 ± 16 g; Table S1). Tags were well within 5-10% of bat body mass
9
10 169 (O'Mara et al., 2014; Sikes et al., 2011).

12 170 A total of 60 SOM-2190 radio-transmitters (Wildlife Materials International, Inc,
13
14 171 Murphysboro, Illinois) were fitted to adult and subadult *E. gambianus* using permanent
15
16 172 collars. Twenty bats were tagged in October 2015 and 40 bats were tagged in February 2016
17
18 173 (18 females; 42 males). Tagged bats were subsequently homed-in on foot during the day to
19
20 174 their roosts using a TRX- 1000S, receiver and a 3-element directional Yagi antenna (Wildlife
21
22 175 Materials International, Inc). For each bat, once the transmitter's signal was homed-in on its
23
24 176 location, efforts were made to visually confirm its location in a tree. This was done to ensure
25
26 177 that signals received from tags were coming from tags that were still attached to bats and not
27
28 178 tags that had fallen under roosts. For each identified roost tree, the GPS location was
29
30 179 recorded. Transmitters had an estimated battery life of between 10-12 months and
31
32 180 radiotracking data were collected over an 11-month period (September 2015 to August 2016).
33
34 181 Bats tagged on October 2015 were tracked for 11 months and those tagged in February 2016
35
36 182 were tracked for 6 months. Twenty bats were initially tracked daily up to 5 days after their
37
38 183 initial release; subsequently, all radio-tagged bats were tracked once-monthly.

184 2.3 Roosting behavior

185 *Epomophorus gambianus* bats could be easily observed and counted in roosting trees once
186 roosts were identified. To describe roosting behavior, the number of bats per tree was counted
187 monthly by a single observer (KAM) over a 32-month period. During this period, any newly
188 identified bat roost within the study area was recorded. Roosting behavior was described
189 using the mean monthly number of bats per roost tree, the maximum number of bats recorded
190 in each roost tree, and how frequently roost trees were utilized as roosts by bats. In addition,

1
2
3 191 the roosting behavior of radio-tagged bats was monitored, including the number of different
4
5 192 roosts used and the frequency with which bats switched roosts between monthly detections.
6
7
8 193 Frequency of roost switching was estimated as the number of times a bat changed roost trees
9
10 194 divided by the total number of times the bat was detected.

11
12 195 Lactating *E. gambianus* females carrying pups could be identified easily in roost trees
13
14 196 during bat roost monitoring. All roosts that were observed to have at least one female bat
15
16 197 carrying a pup during the study period were delineated as maternity roosts and those in which
17
18 198 no nursing females were seen were delineated as non-maternity roosts. Once pups were
19
20 199 weaned it became difficult to visually distinguish female bats from sexually immature males
21
22 200 of similar sizes within the roost trees. Hence our designation of roosts as maternity roost is
23
24 201 based solely on the presence of lactating females with pups at roosts. This categorization of
25
26 202 maternity and non-maternity roosts allows for the comparison of the characteristics of roost
27
28 203 sites used by *E. gambianus* for both purposes. This distinction is important as any observed
29
30 204 differences in features selected could have implications for differences in management
31
32 205 strategies for the conservation of the species.

33
34
35
36
37 206 For each bat roost found, the tree species was identified and measurements of the tree
38
39 207 height (HT), trunk diameter at breast height (DBH) and the crown diameter (CD) were taken.
40
41 208 These parameters were chosen as they are commonly used to assess the structural
42
43 209 characteristics of tree roosts (Hahn et al., 2014; Lucas et al., 2015; Sedgely & O'Donnell,
44
45 210 2004). Tree height was measured using a Nikon® Forestry Pro laser rangefinder, DBH was
46
47 211 measured at 1.4 m above the ground and crown diameter was measured as the longest on-the-
48
49 212 ground extent across the crown of each tree using a tape measure. The Global Positioning
50
51 213 System (GPS) locations for all roosts and non-roost trees and for all buildings (houses,
52
53 214 homesteads and shops) within the study area were recorded. GPS coordinates were uploaded
54
55 215 into PC-GPS software Garmin BASECAMP version 4.6.2 (Garmin Ltd) for spatial analysis
56
57
58
59
60

1
2
3 216 in Quantum GIS software (QGIS version 2.12.2-Lyon). Distance from trees to buildings (DB)
4
5 217 were extracted using the linear distance matrix in QGIS. A 17.8 m radius circular buffer (ca
6
7 218 0.1-ha area) was delineated around each roost tree to create roost plots. For each plot, the
8
9 219 total tree basal area "BA" (m²/ha) and the tree density "TD" (trees/ha) per plot were
10
11 220 calculated using the "points in polygon" tool in QGIS.
12
13

14 221 For comparison, we selected all trees within the study area ($N = 957$) with DBH > 0.1
15
16 222 m and height > 4.2 m that were not used as roosts. These minimum heights and DBH criteria
17
18 223 were chosen because they were the minimum recorded for roost trees. All trees not used as
19
20 224 roosts that were selected for comparison (comparison trees) and their corresponding plots
21
22 225 were assessed for the same characteristics as roost trees and roost plots.
23
24

26 226 **2.4 Data analysis**

28 227 **2.4.1 Roosting behavior and tree characteristics**

30 228 We combined radiotracking data obtained from bats initially tracked daily together with those
31
32 229 tracked monthly. Hence radio-tracking data was standardized as bat-days (1 bat day = 1 day of
33
34 230 radiotracking data from 1 bat). Frequency of roost switching was estimated as number of
35
36 231 switches made by a bat between successive detections divided by the total number of bat-
37
38 232 days it was detected. Frequency of switching was estimated for only tagged bats that were
39
40 233 located at least two times during the study ($N = 30$).
41
42
43

44 234 Univariate analysis (Mann-Whitney U test for 2 independent samples) was used to
45
46 235 compare differences in roosting behavior of radio-tagged bats, roost tree versus non-roost tree
47
48 236 characteristics, and for maternity roosts versus non-maternity roosts. For roost trees and non-
49
50 237 roost trees, comparisons were made for differences in tree height, DBH, crown diameter,
51
52 238 distance to nearest building, plot tree density and plot total basal area. Comparisons were also
53
54 239 made for differences in the mean monthly number of bats per tree (A_vN), maximum number
55
56 240 of bats recorded at roost (MaxB), frequency of occupancy of roost (FO) and the distance to
57
58
59
60

241 the nearest neighboring roost tree (DNR) for maternity and non-maternity roost trees.

242 Parameters of bat roosting behavior are reported with descriptive statistics and where

243 appropriate, means \pm *SD*.

244 **2.4.2 Preference for tree species as roosts**

245 To test if there was a preference of tree species used as roosts by the bats, a binomial exact

246 test was used to compare the use of each roost tree species that was identified, relative to their

247 availability in this order: preferred, random, or infrequently selected. Comparison trees were

248 combined together with roost trees to establish availability of all tree species for this analysis.

249 If the proportion of a tree species used was significantly greater than expected based on its

250 availability, the species was described as "Preferred". If there was no significant difference in

251 the relative use and availability, the species was described as being used at "Random".

252 However, if a tree species' use was significantly less than expected based on its availability, it

253 was considered as "Infrequently selected" (Hahn et al., 2014; Neu et al., 1974; Sedgely &

254 O'Donnell, 2004). Exact tests were performed in Minitab statistical package (version 16.1)

255 and all tests were conducted with a 95% CI. We also used this approach when considering the

256 characteristics of maternity roost and non-maternity roosts.

257 **2.4.3 Roost selection**

258 Logistic regression was used to determine which of the tree variables measured best

259 differentiated characteristics of roost and non-roost trees and to predict roost selection by *E.*

260 *gambianus*. Seven variables were included in the global model (full model) and subset

261 models were obtained using the dredge function in the "MuMIn" package (Bartoń, 2009).

262 Model selection was based on AIC values. Model averaging of the best models (Δ AIC \leq

263 2) was done to obtain parameter estimates, unconditional standard errors of the predictor

264 variables and their 95% CI. The relative importance of each parameter was assessed using the

265 "importance" function in the "MuMIn" package (Bartoń, 2009). We considered a predictor

1
2
3 266 variable as having a significant effect on roost selection if the associated 95% CI did not
4
5
6 267 overlap with zero.

7
8 268 Similarly, we ran a logistic regression on tree characteristics for maternity and non-
9
10 269 maternity roost trees to identify roost tree variables that were important for maternity roost
11
12 270 selection. Eight parameters were included in the global model; the maximum number of bats
13
14 271 per tree (MaxN) and plot basal area (BA) were collinear to mean monthly number of bats per
15
16 272 roost and plot tree density respectively and hence were excluded from the global model.
17
18 273 Subset models of the global model were ranked by AICc. Selection of best models, model
19
20 274 averaging and parameter significance followed a similar procedure to that conducted for the
21
22 275 roost tree selection.
23
24
25
26 276

27 28 29 277 **3. RESULTS**

30 31 32 33 279 **3.1 Roosting behavior**

34
35 280 A total of 152 roost trees were identified; 139 from roost searches and an additional 13 from
36
37 281 tracking radio-tagged bats to their roosts. Seventy-seven of these roost trees were utilized as
38
39 282 maternity roosts. Between one to 1,122 bats were recorded at roost trees with mean of 80 bats
40
41 283 per tree. The mean monthly number of bats per roost tree ranged from one to 256 bats per
42
43 284 tree over the monitoring period (Figure 1a). The frequency of occupancy of roosts ranged
44
45 285 from 3.1% to 100% (Figure 1b). Roosts were typically made up of a mix of both males and
46
47 286 females. *Epomophorus gambianus* co-roosted with Peter's lesser epauletted fruit bat
48
49 287 (*Micropteropus pusillus*) at twenty-six of these roosts, however both species were spatially
50
51 288 separated within the roost tree and never mixed.
52
53
54

55
56 289 Out of the 60 bats that were radio-tagged, 40 (28 males, 12 females) were re-detected
57
58 290 during the study period. Radio-tagged bats were successfully located on 139 bat days at 51
59
60

1
2
3 291 different roosts, 19 of which were used by more than one radio-tagged bat (Figure 2). The
4
5 292 frequency of switching roosts varied from 0 to 0.86 bat days ($N=30$ bats). Frequency of
6
7
8 293 switching was higher in males (mean = 0.49 ± 0.23 bat days, $N=23$) than in females (mean =
9
10 294 0.33 ± 0.18 bat days, $N=7$) suggesting that males were more likely than females to switch
11
12 295 roosts. On average, there was a 93% chance of a bat switching to a previously unused roost
13
14 296 when switching. The mean linear distance between roosts used by male bats (255 ± 254 m)
15
16 297 was significantly longer than that for female bats (102 ± 71 m) ($t = 4.50$, $df = 86$, $P < 0.0001$).
17
18 298 Roost sharing by both sexes of radio-tagged bats was observed at five different roost trees
19
20 299 and up to seven radio-tagged bats of both sexes shared the same roost on three different
21
22 300 occasions.

301 **3.2 Roost characteristics and selection**

302 A total of 1,109 (roost and comparison) trees were identified and assessed within the study
303 area. However, due to tree losses during the study period, not all trees could be assessed for
304 all parameters. Binomial exact tests indicated that roost selection with respect to tree species
305 was non-random. Neem (*Azadirachta indica*), mango (*Mangifera indica*), fig (*Ficus sp.*),
306 Indian mast (*Polyalthia longifolia*) and African tulip (*Spathodea campanulata*) trees were
307 used as roosts in significantly higher proportions than they were available (Table 2). These
308 five preferred species made up only 31% of the total number of trees assessed in the study
309 area but constituted 57% of all roost trees. Bats showed less preference for oil palm trees
310 (*Elaeis guineensis*), soursop (*Annona muricata*), coconut (*Cocos nucifera*) and the African
311 copaiba balsam (*Daniellia oliveri*) trees. Twenty-four other tree species were used at random
312 as the proportion of their use was not significantly different to their availability. Fifty-seven
313 tree species were not used, but there was no evidence to indicate that these trees were actively
314 avoided. Tree species used as maternity roosts did not differ from those utilized as non-
315 maternity roosts.

1
2
3 316 With the exception of tree plot basal area, all other roost tree characteristics differed
4
5 317 significantly from non-roost (comparison) trees. Roost trees were significantly taller ($P <$
6
7 318 0.0001), had significantly larger DBH ($P < 0.0001$), larger crown diameters ($P < 0.0001$),
8
9 319 lower plot tree densities ($P < 0.0001$) and were closer to buildings ($P < 0.0001$) compared to
10
11 320 non-roost tree characteristics (Table 1). For tree species that were identified as preferred,
12
13 321 species-level comparisons (using effect size estimates based on Wendt, 1972's rank biserial
14
15 322 formula) for characteristics of roost and non-roost trees showed similar results (Table S2).

16
17
18
19 323 Six parameters were present in the top model set for the model averaging for roost
20
21 324 selection (Table S3). Tree height, crown diameter, distance to building, DBH, and plot total
22
23 325 basal area had the highest relative importance compared to plot tree density (19% relative
24
25 326 importance). Based on calculated 95% CI, all the variables, with the exception of plot tree
26
27 327 density, were significant predictors of roost selection (Table 3). A one-unit increment in
28
29 328 height, DBH and crown diameter of a tree increased the odds of being utilized as a roost by
30
31 329 1.2, 13.3 and 1.1 respectively; trees that had bigger trunk diameters, larger crowns and were
32
33 330 taller were more likely to be used as roosts. Plot total basal area and distance to building had
34
35 331 inverse effects on selection; increase in plot basal area reduced probability of selection and
36
37 332 trees closer to buildings were more likely to be used as a roost.

333 3.3 Maternity roost characteristics and selection

334 Univariate analysis indicated differences in characteristics of maternity and non-maternity
335 roost trees. Maternity roost trees were significantly bigger DBH ($P = 0.03$) and were located
336 in plots with significantly fewer trees ($P = 0.04$) compared to non-maternity roost trees.
337 Maternity roosts were more-frequently occupied by bats ($P < 0.0001$), had a higher average
338 monthly number of bats ($P < 0.0001$), and higher maximum number of bats ($P < 0.0001$)

1
2
3 339 compared to non-maternity roosts (Table 4). Other characteristics did not differ significantly
4
5 340 between the two groups.
6

7
8 341 Tree height, crown diameter and frequency of occupancy were not present in the best
9
10 342 models (Table S4) indicating that these parameters were poor predictors of maternity roost
11
12 343 selection. Model averaged estimates of parameters indicated that the mean monthly number
13
14 344 of bats recorded was the single most important parameter and the only significant predictor of
15
16 345 maternity roost selection. All other parameters that were present in the best models had
17
18 346 confidence intervals that included zero, indicating little support that these parameters affected
19
20 347 maternity roost selection (Table 5).
21
22
23

24 348

26 349 4. DISCUSSION

28 350

31 351 4.1 *Epomophorus gambianus* roosting behavior and roost selection

32
33 352 *Epomophorus gambianus* is often described as roosting in loose colonies of individuals or a
34
35 353 few individuals, with large colonies, comprising multiple roosts, containing up to a few
36
37 354 hundred individuals (Boulay & Robbins, 1989; Marshall & McWilliam, 1982; Rosevear,
38
39 355 1965; Thomas & Fenton, 1978). Although we report similar roosting behavior in this species
40
41 356 in the current study, we also show that single roosts can be much larger, containing over a
42
43 357 thousand individuals, and that colonies can be five times as big as these large roosts. Our
44
45 358 observation of *E. gambianus* co-roosting with *M. pusillus*, has been reported previously
46
47 359 (Boulay & Robbins, 1989) and suggests that both species have similar roosting requirements.
48
49

50
51 360 Although the frequency of occupancy at roost sites was generally high, fidelity to
52
53 361 specific roost trees was rather low, with bats utilizing several roosts and switching frequently
54
55 362 between them. An earlier study reported similar behavior in this species, with bats switching
56
57 363 between several roosts almost each day (Thomas & Fenton, 1978). In a review of site fidelity
58
59
60

1
2
3 364 by bats (Lewis, 1995), *E. gambianus* was described as a species that frequently changed
4
5 365 roosts. Generally, roost switching is known to be high among tree roosting bats (Kunz, 1982;
6
7 366 Menzel et al., 1998), and this has been documented for several species, including, Wahlberg's
8
9 367 epauletted fruit bat *Epomophorus wahlbergi* (Fenton et al., 1985), *Hypsignathus monstrosus*
10
11 368 (Bradbury, 1977), fringed myotis *Myotis thysanodes* (Lacki & Baker, 2007), lesser long-
12
13 369 eared bat *Nyctophilus geoffroyi* (Lumsden & Bennett, 2006), big brown bat *Eptesicus fuscus*
14
15 370 (Vonhof & Barclay, 1996), and greater short-nosed fruit bat *Cynopterus sphinx* (Storz et al.,
16
17 371 2000).

18
19
20
21 372 For tree roosting species, fidelity to an area, rather than to a single tree, is common
22
23 373 (Hein et al., 2008; Kunz, 1982; Vonhof & Barclay, 1996) for reasons including decreased
24
25 374 predation, decreased disturbance, reducing ectoparasite loads, familiarity with different roost
26
27 375 microclimates, and reducing commuting costs to foraging sites (Kunz & Lumsden, 2003;
28
29 376 Lewis, 1995). Patterns of roost switching and aggregation among radio-tagged bats, together
30
31 377 with the observed variation in mean numbers and frequency of roost occupancy, suggest a
32
33 378 fission-fusion behavior in *E. gambianus*. Although this behavior is widespread in bats, much
34
35 379 remains to be understood and future studies on this could help in understanding the complex
36
37 380 social structures, group decision making, and cooperation among bats (Kerth, 2008; Kerth &
38
39 381 Barbara, 1999).

40
41
42
43 382 As we hypothesized, roost selection by *E. gambianus* was not random. Collectively,
44
45 383 *E. gambianus* roost trees were bigger and taller, had larger crown diameters, were closer to
46
47 384 buildings, and located in plots with lower tree densities than trees that were not used as
48
49 385 roosts. Logistic regression indicated tree trunk size (DBH), tree height, crown diameter, plot
50
51 386 basal area and distance to nearest building as the most important factors that differentiated
52
53 387 roost trees from non-roost trees and these parameters predicted roost selection for *E.*
54
55 388 *gambianus*. These predictor variables occurred at different scales; at the tree scale (height,
56
57
58
59
60

1
2
3 389 DBH, crown diameter), plot scale (plot basal area), and landscape scale (distance to
4
5 390 buildings). This suggests that *E. gambianus* selects roosts by considering factors from
6
7 391 different spatial scales, supporting the view that resource selection occurs at multiple scales
8
9 392 (Limpert et al., 2007; Lucas et al., 2015; Manly et al., 1993). Although very few landscape-
10
11 393 level factors were considered in this study owing to the relatively small study area, we
12
13 394 anticipate that, at a much larger scale, the effects of other landscape factors, such as distance
14
15 395 to water and feeding areas (e.g. Kalcounis-Rüppell et al., 2005), might also influence roost
16
17 396 selection.

18
19
20
21 397 The occurrence of roost trees was higher in plots that had lower basal area and lower
22
23 398 tree density, although we found little support for the latter. This suggests a preference for
24
25 399 roosting in bigger and taller trees located in relatively open and less mature plots rather than
26
27 400 in mature, dense plots. Management efforts targeted at trees within such plots could be
28
29 401 important for the conservation of the species. We also found significant support for the
30
31 402 selection of trees closer to buildings as roosts by *E. gambianus*. The formation of roosts in
32
33 403 close proximity to humans is very common among pteropodid bats. *Eidolon helvum* and
34
35 404 several *Pteropus* species form very large colonies in urban centres (Hahn et al., 2014; Pierson
36
37 405 & Rainey, 1992; Rosevear, 1965). The reason for this behavior is unclear for some species
38
39 406 like *Eidolon helvum* which forage over large distances (Calderón-Capote et al., 2020).

40
41 407 *E. gambianus* might roost closer to urban and peri-urban areas because household
42
43 408 backyard gardens offer an oasis of fruit diversity and alternative food sources, especially as
44
45 409 natural food resources diminish due to foraging habitat loss and agricultural intensification
46
47 410 (Hahn et al., 2014; Kessler et al., 2018; Plowright et al., 2014). Unfortunately, foraging
48
49 411 distances for *E. gambianus* and the feeding habits of this species are not well known (but see
50
51 412 Amponsah-Mensah et al., 2019; Thomas & Fenton, 1978), and further work is required to
52
53 413 verify this assumption. *Epomophorus gambianus* exhibited preference for trees which were
54
55
56
57
58
59
60

1
2
3 414 closer to buildings. This could be because predation risk might be reduced if natural predators
4
5 415 avoid areas close to human habitation (Voigt et al., 2015) except where significant hunting by
6
7 416 humans or predation by domestic animals (e.g., cats; see Ancillotto et al., 2013) occurs. Trees
8
9
10 417 close to buildings are commonly planted as ornamental trees and to provide shade within the
11
12 418 compounds of houses or of several households, or as fruit trees. The utilization of roosts close
13
14 419 to human habitation could be the result of loss of suitable bat roosting and feeding habitat or
15
16
17 420 the encroachment of humans into bat habitat. Habitat loss has been identified as one of the
18
19 421 leading problems bats face globally, driving population declines of several species (Kunz et
20
21 422 al., 2011; Mickleburgh et al., 1992, 2002).

23
24 423 The use of tree species for roosting by *E. gambianus* was not at random; this bat
25
26 424 species preferred neem, mango, African tulip tree, Indian mast tree, and fig trees over other
27
28 425 tree species even though the preferred species made up less than 32% of all trees within the
29
30 426 area. Oil palm, soursop, coconut and African copaiba balsam trees were infrequently selected
31
32
33 427 and many other species were not used as roosts by bats in this study. Although we identified a
34
35 428 preference for specific tree species, our findings also indicates that other tree species can be
36
37 429 utilized by the species. Preference for specific tree species has been reported previously (e.g.
38
39 430 Vonhof & Barclay, 1996) but, as in this study and others (e.g. Sedgeley & O'Donnell, 1999),
40
41 431 preference can be an artefact of the physical, plot or landscape level characteristics and not
42
43 432 just the species per se. Tree species that typically attain physical characteristics or occur in
44
45 433 plots that make them suitable for roosting by bats, may be preferred over others. Hence,
46
47 434 where these tree species are not available or do not meet preferred characteristic
48
49 435 requirements, other species may be utilized as roosts. Elsewhere in Ghana, *E. gambianus* has
50
51 436 been reported to roost in neem and fig trees but also in mahogany (*Khaya senegalensis*) trees
52
53 437 (Ayensu, 1974; Baker & Harris, 1957; Marshall & McWilliam, 1982) and outside Ghana, in
54
55 438 sausage tree *Kigelia africana* and *Cola* sp. (Rosevear, 1965; Thomas & Fenton, 1978).

1
2
3 439 In addition to the morphological features of trees measured in this study, other
4
5 440 features of trees such as shape, canopy cover (see Kalcounis-Rüppell et al., 2005), or fruiting
6
7 441 phenology could potentially influence roost tree selection by bats. For instance, Marshall &
8
9 442 McWilliam (1982) described *E. gambianus* roosting high up in "umbrella shaped trees" and
10
11 443 Boulay & Robbins (1989) described the species hanging from branches in trees well shaded
12
13 444 by foliage. This suggests that shape of tree, canopy cover or degree of shade provided by
14
15 445 trees could influence their selection for roosting. Tree-roosting bat species are known to
16
17 446 switch or abandon roosts when roosts are defoliated, hence tree species that lose their leaves
18
19 447 (e.g., deciduous species) may be avoided or less preferred (Kunz, 1982). The preferred tree
20
21 448 species identified as being used by *E. gambianus* in this study are evergreen or semi-
22
23 449 evergreen species, which might also influence their selection.
24
25
26
27
28

29 450 **4.2 Sex related and maternity roost selection**

30 451 As predicted, maternity roosts were a subset of all roost trees, most significantly, those roosts
31
32 452 that contained a higher number of bats. Since maternity roosts are only a subset of all roost
33
34 453 trees, we propose that reproductive females of this species may exhibit aggregation patterns
35
36 454 at large roost where they may form mixed-sex aggregations rather than single-sex maternity
37
38 455 roosts during reproduction seasons. Our observation of some radio-tagged bats aggregating at
39
40 456 some roosts in this study provides anecdotal evidence for this and further studies will be
41
42 457 required to provide more insight.
43
44
45
46

47 458 On the basis that *E. gambianus* roost in loose colonies where individuals are well
48
49 459 spaced from each other (Happold, 2013), the selection of large colonies by nursing female
50
51 460 bats is likely a predator avoidance strategy rather than for physiological benefits such as
52
53 461 thermoregulation, which often explains aggregation in temperate zone species. An advantage
54
55 462 of selecting large roosts is that nursing females and their young are more likely to be better
56
57 463 protected from predation by decreasing the risk of attack of any individual (Fenton et al.,
58
59
60

1
2
3 464 1994; Wilkinson & South, 2002) or by providing increased vigilance (Klose et al., 2009).
4
5 465 Alternatively, the selection of roosts with more bats may also reflect social co-operation
6
7 466 needs, such as offering the opportunity for young bats to learn and socialize with each other
8
9 467 (Kerth, 2008) which is likely to be important in such a social and colonial roosting species.
10
11 468 Hence trees that contain large roosts could be vital to the sustainability of the colony and
12
13 469 should be prioritized in conservation management practices.
14
15

16
17 470 The use of a smaller roosting area by female bats has been hypothesized to be a
18
19 471 strategy for reducing the energetic constraints when roost-switching while carrying pups
20
21 472 (Henry & Kalko, 2007). This is consistent with our observation of shorter distances between
22
23 473 roosts used by radio-tagged female bats compared to male bats. Utilizing a smaller roosting
24
25 474 area and travelling shorter distances between roosts also has the advantage of reducing the
26
27 475 risk of detection by predators. Although the extent of predation was not assessed during the
28
29 476 current study, some observations were made of pied crows (*Corvus albus*) attacking juvenile
30
31 477 bats in roosts. Also, the yellow-billed kite (*Milvus migrans*) and shikra (*Accipiter badius*)
32
33 478 were seen to attack bats in flight when roosts were disturbed. The extra weight of carrying a
34
35 479 pup can reduce the agility and maneuverability needed to evade an aerial attack by predators.
36
37 480 Roosts used by male bats might be dispersed over a larger area due to their propensity to
38
39 481 utilize multiple roosts compared to female bats and their use of calling roosts for courtship
40
41 482 displays.
42
43
44
45

46
47 483 In conclusion, our study confirms that roost selection by *E. gambianus* is not random
48
49 484 as the species selects trees with characteristics that differentiate roost trees from non-roost
50
51 485 trees. Trees used as roosts were more likely to be closer to buildings and to occur in open and
52
53 486 less mature plots than non-roost trees, thus highlighting the species' ability to persist in
54
55 487 human modified landscapes and in close proximity to people. Based on our findings, ensuring
56
57 488 the preservation of large roosts can be important for maintaining maternity roosts whilst
58
59
60

1
2
3 489 management practices that preserve trees with the preferred characteristics in open and less
4
5 490 mature plots can provide roosting opportunities for *E. gambianus* within modified
6
7 491 landscapes. Our findings contribute knowledge of how wildlife utilize human-modified
8
9 492 landscapes which is vital to better predict and improve the management of biodiversity in the
10
11 493 Anthropocene.

494 **TABLES**

495

496 Table 1. Differences in characteristics between roost and non-roost trees. Comparisons were
 497 made using Mann-Whitney U tests. Seven roost trees which were lost before some
 498 parameters could be measured are not included.

Roost Parameter	Roost, <i>N</i> = 145		Non roost <i>N</i> = 957		<i>P</i>
	median	IQ range	median	IQ range	
Tree Height (m)	10.4	8.80-12.40	7.8	6.2-10	<0.0001
Tree DBH (m)	0.48	0.35-0.71	0.3	0.24-0.09	<0.0001
Tree Crown diameter (m)	10.25	7.5-13.1	7.6	5.4-9.9	<0.0001
Plot tree density (Trees/ha)	40	20-70	60	30-90	<0.0001
Plot basal area (m ² /ha)	7.2	3.5-11	7.4	3.2-13	0.66
Distance to nearest building (m)	12.529	6.4-23	17.0	10.36-27.28	0.0001

499

Table 2. Roost tree selection by *E. gambianus* showing preferred, random, and infrequently selected species. Selection is based on the use of a tree species as a roost compared to its abundance within the study area. Tests are based on binomial exact tests. Only species with abundance ≥ 4 are shown. Fifty-seven tree species unused by bats for roosting are not included here.

<i>Plant species</i>	Proportion of all trees	Proportion of roost trees	<i>P</i>	Preference

Table S2 Probability of superiority (or common language effect size) estimation for species-level comparisons of roost and non-roost tree characteristics for preferred tree species. r is rank biserial correlation based on Wendt (1972)'s formula ($r = 1 - (2U) / (n_1 * n_2)$); n_1, n_2 = sample sizes of the 2 groups, U = Mann-Whitney U . $Pa > b$ is the probability of superiority or common language effect size and gives the percentage of occasions when a randomly sampled member of the distribution with the higher median will have a higher score than a randomly sampled member of the other distribution. Higher median values for each pair of comparisons are shown in bold.

Tree species	<i>N</i>	Tree Height				Tree DBH			
		Median (IQR)		<i>r</i>	<i>Pa > b</i>	Median (IQR)		<i>r</i>	<i>Pa > b</i>
		Roost	Non roost			Roost	non roost		
<i>Azadirachta indica</i>	22	10.1 (9.4-10.65)	51 9.2 (7.9-10.4)	0.28	63.9	0.4 (0.31-0.51)	0.34 (0.22-0.48)	0.23	61.6
<i>Ficus spp</i>	12	9.5 (7.05-11.45)	15 6.8 (6-7.8)	0.49	74.4	0.645 (0.49-0.76)	0.31 (0.22-0.48)	0.84	91.9
<i>Mangifera indica</i>	41	9.4 (8.2-11)	177 7.0 (5.7-8)	0.67	83.6	0.64 (0.41-0.89)	0.33 (0.25-0.46)	0.65	82.5
<i>Polyalthia longifolia</i>	9	14.2 (12.24-15.09)	10 10.0 (8.15-14.7)	0.44	72.2	0.27 (0.25-0.43)	0.33 (0.25-0.40)	0.09	54.4
<i>Spathodea campanulata</i>	4	15.6 (10.55-17.5)	3 8.0 (7.2-14.8)	0.67	83.3	0.89 (0.74-0.99)	0.28 (0.27-0.53)	1.00	100.0
