Abstract

Aim: This study aims to investigate associations of formal childcare with maternal and child outcomes in a large sample of adolescent mothers.

Background: Forty percent of adolescent girls in Africa are mothers. Increasing evidence shows positive impacts of formal childcare use for adult women, but no known studies in the Global South examine associations for adolescent mothers and their children.

Methods: We interviewed 1046 adolescent mothers and completed developmental assessments with their children ($n = 1139$) in South Africa's Eastern Cape between 2017 and 2019. Questionnaires measured childcare use, maternal and child outcomes and socio-demographic background variables. Using cross-sectional data, associations between formal childcare use and outcomes were estimated in multivariate multi-level analyses that accounted for individual-level and family-level clustering.

Results: Childcare use was associated with higher odds of being in education or employment (AOR: 4.01, 95% CIs: 2.59–6.21, $p < .001$), grade promotion (AOR: 2.08, 95% CIs: 1.42–3.05, $p < .001$) and positive future ideation (AOR: 1.58, 95% CIs: 1.01–2.49, $p = .047$) but no differences in mental health. Childcare use was also associated with better parenting on all measures: positive parenting (AOR: 1.66, 95% CIs: 1.16–2.38, $p = .006$), better parental limit-setting (AOR: 2.00, 95% CIs: 1.37–2.93, $p < .001$) and better positive discipline (AOR: 1.77, 95% CIs: 1.21–2.59, $p = .003$). For the children, there were no differences in temperament or illness, but a significant interaction showed stronger associations between childcare use and better cognitive, language and motor scores with increasing child age (AOR: 5.04, 95% CIs: 1.59–15.96, $p = .006$).

Conclusions: Adolescent mothers might benefit substantially from formal childcare, but causal links need to be explored further. Childcare use was also associated with improved parenting and better child development over time, suggesting positive pathways for children. At an average of \$9 per month, childcare provisions for adolescent mothers may offer low-cost opportunities to achieve high returns on health and human capital outcomes in Sub-Saharan African contexts.

KEYWORDS

adolescent mothers, adolescent pregnancy, human capital, school policies, South Africa

1 | INTRODUCTION

By the age of 20, 46% of adolescent girls in Sub-Saharan Africa are already mothers (UNFPA, 2022), with emerging evidence suggesting that COVID's socio-economic impacts have further increased adolescent pregnancy (Zulaika et al., 2022). Adolescent motherhood is frequently preceded by severe adversity, including poverty, orphanhood and child abuse (Thurman et al., 2006). Globally, adolescent motherhood is a marker of disadvantage, with higher levels of school dropout, unemployment, mental health challenges (Ardington et al., 2015; Huda et al., 2021) and lower future aspirations (Mchunu et al., 2012). In turn, adolescent parenthood predicts disadvantage in the next generation, with children of adolescent parents showing poorer health (Kurth et al., 2010), cognitive development and school readiness (Fall et al., 2015; Lipman et al., 2011). Pathways from maternal to child disadvantage have been examined—mostly in high-income settings—identifying that adolescent parents have higher long-term poverty, lower readiness for childrearing (Blum & Gates, 2015) and—often driven by poverty—lower parenting skills such as limit-setting, cognitive stimulation and sensitivity with infants, compared with older parents (Barlow et al., 2011; Oxford & Spieker, 2006).

Despite the scale of the challenge, interventions in the region have focused on preventing teenage pregnancy, rather than on supporting adolescent parents (Mmari & Sabherwal, 2013). However,

Key Messages

- Approximately one in three adolescent mothers reported using formal childcare services, paying an average of \$9 a month.
- Multivariate multi-level analyses identified associations of childcare use with improved education/employment outcomes, positive future outlook, parenting behaviours for young mothers and positive development for their children over time.
- International demands for affordable childcare should include considerations for adolescent parents, particularly in Sub-Saharan Africa where rates of adolescent pregnancy remain high.
- Exploring the benefits of childcare for adolescent parents in different contexts, using different methodologies, is essential to cement calls for universal childcare as a cost-effective and sustainable intervention.

multiple systematic reviews of adolescent pregnancy prevention have shown no significant effects of any program in the Global South (DiCenso et al., 2002; Oringanje et al., 2016; Ramos, 2011).

We lack an evidence base for services that can promote health and human capital development for adolescent mothers and their children.

For adult mothers, there is increasing international evidence that access to formal childcare for their children is associated with gains. Access to childcare is poorer in low-income countries where about eight out of 10 children who need childcare do not have access to it (Devercelli & Beaton-Day, 2020). Compared with high-income countries, children from low-income countries are five times less likely to be in childcare (Devercelli & Beaton-Day, 2020). A recent study showed that, across 53 low- and middle-income countries, 20% of children below age five were either left alone or left in the care of a sibling below the age of 10 for at least an hour per week (Samman et al., 2016). Data on the cost of formal childcare are limited, especially in the Global South (Devercelli & Beaton-Day, 2020), but high cost remains a major concern for women in many Sub-Saharan countries (Samman et al., 2016). Parents might also be discouraged by low-quality childcare, which has been shown to affect child development negatively (Britto et al., 2017).

Centre-based childcare has received limited attention in policy and research across low- and middle-income countries (Bhan et al., 2020; Hughes et al., 2021). One recent study found that nearly half of working parents, and even one in five unemployed parents in a Nairobi slum, regularly used paid childcare (Clark et al., 2021). A systematic review of impacts of childcare provision for adult mothers in the Global South found increased maternal employment in all four identified studies (Evans et al., 2021). In Kenya, a randomized trial of the provision of subsidized childcare vouchers for adult women found an 8.5% increase in employment (Clark et al., 2019). In Brazil, Mexico and Guatemala, adult mothers with access to formal childcare had higher employment and self-esteem (Angeles et al., 2014; Hallman et al., 2002; Sanfelice, 2019). In Mozambique, a randomized controlled trial of a preschool intervention increased labour supply of primary caregivers and improved some parenting skills (Martinez et al., 2012). This evidence does span a wide range of formal childcare services, from those with strong early childhood development curricula to low-income small private childcare centres in the homes of local women. However, none of these studies included adolescent parents.

A systematic review of impacts of formal childcare use on child development (Brown et al., 2014) found only one study in the Global South, showing improved cognitive outcomes (Mwaura et al., 2008). Other evidence is mixed, with some studies showing no differences in child development (Angeles et al., 2014), whereas others show some improvements (Martinez et al., 2012; Mwaura et al., 2008). Several studies show no differences in child health (Nakahara et al., 2010). Again, none of the literature reported outcomes for the children of adolescent mothers, but there is some evidence from the Global North that formal childcare attendance may be associated with long-term improved educational and economic outcomes (Domond et al., 2020).

Our scoping review,¹ summarized above, identified no known research in the Global South that examines associations of access to formal childcare with outcomes for adolescent mothers, or the children of adolescent mothers. This study aims to start filling this gap through the following objective: to investigate associations of using formal childcare with maternal education, employment, future ideation, mental health and parenting and with child temperament, illness and cognitive, language and motor development in a large sample of adolescent mothers in South Africa's Eastern Cape Province.

2 | METHODS

2.1 | Patient and public involvement statement

Before data collection commenced, a Teen Advisory Group was set up, consisting of a group of adolescent mothers (all had their first child below the age of 19 but were up to 24 years old at the time of the baseline data collection). These young mothers provided feedback throughout the conceptual design of the study and gave input on the questionnaire items, design and interview practices. Two mothers were involved as co-authors of this paper and commented on the analytical approach, study findings and interpretations.

2.2 | Study design and sample size

This study used cross-sectional data from the first wave of a prospective cohort study, collected between 2017 and 2019. A power analysis using G*Power 3.1.6 (Faul et al., 2009) used assumptions of 80% power, a Cohen's f .09 small effect size for maternal health outcomes, sub-group analyses for HIV-positive adolescent mothers and a conservatively estimated 10% attrition rate. This shows that a sample of at least 1000 adolescent mothers allowed for testing of the desired parameters (Jackson, 2003). The final sample consists of 1046 adolescent girls and young women (aged 10–24). All participants had their first pregnancy before the age of 20 (World Health Organization, 2020) but were aged up to 24 years at the time of data collection. We also collected data from the adolescent mothers' children ($n = 1139$) in addition to their completion of a developmental assessment.

2.3 | Setting and sample

Adolescent girls and young women were recruited from urban and rural locations of two health districts in Eastern Cape South Africa. Based on formative work with an advisory group of adolescent mothers, six parallel recruitment channels were deployed to ensure the inclusion of hard-to-reach adolescents and to minimize recruitment bias. Recruitment took place through maternity obstetric units ($n = 9$) (UNFPA, 2022); all public district health facilities ($n = 73$)

(Zulaika et al., 2022); a randomly selected subsample of secondary schools in the district ($n = 43$) (Thurman et al., 2006); referrals by social workers and NGOs (Ardington et al., 2015); door-to-door recruitment (Huda et al., 2021); and community referrals by adolescent mothers themselves (Mchunu et al., 2012), which were particularly valuable in areas with low service access. Adolescent girls and young women were eligible for inclusion in the study if they were aged 10–24 at the time of the study, with at least one child who was conceived prior to the age of 20. Only participants residing in the Buffalo City Municipality or Amathole Health District were included in the study. Refusals and successful recruitment rates were recorded for each channel (see participant flowchart in Figure 1) showing that between 95% and 98% of all eligible mothers identified through each channel were successfully enrolled in the study.

2.4 | Ethical considerations

This project involved working with a particularly vulnerable group. Adolescent pregnancy is associated with a range of adversities, including poverty, HIV risks and violence exposure. Our study site is based in the Eastern Cape, one of South Africa's poorest provinces where adolescent mothers have limited access to support sources and high rates of HIV pervade. Minimizing the risks for participants was an

ethical imperative throughout the planning, data collection, storage, analysis and dissemination stages of all our research studies. Voluntary informed consent was sought from adolescents who were above the age of 18, and assent was provided by underage participants in addition to consent from their adult caregiver. All consent forms were available in English and Xhosa and were read aloud in cases of low literacy. Ethical approval was provided by the University of Oxford and the University of Cape Town (R48876/RE001; R48876/RE002; HREC REF: 226/2017) and the Eastern Cape Provincial Departments of Health, Basic Education, and Social Development.

2.5 | Data collection procedures

Participants were interviewed in private spaces in and around their own home, or in a place of their choosing. Adolescents completed two questionnaires lasting about 60 min each, using audio mobile-assisted self-interviewing on electronic tablets, assisted by local interviewers trained to adjust the level of assistance by age and literacy abilities of participants. In addition, all children completed developmental assessments based on the Mullen Scales for Early Learning (Mullen, 1995), which took between 15 and 60 min, depending on the child's age and were scored by trained local research assistants. Please see Table 1 for a description of all items, scales and measures used in the study.

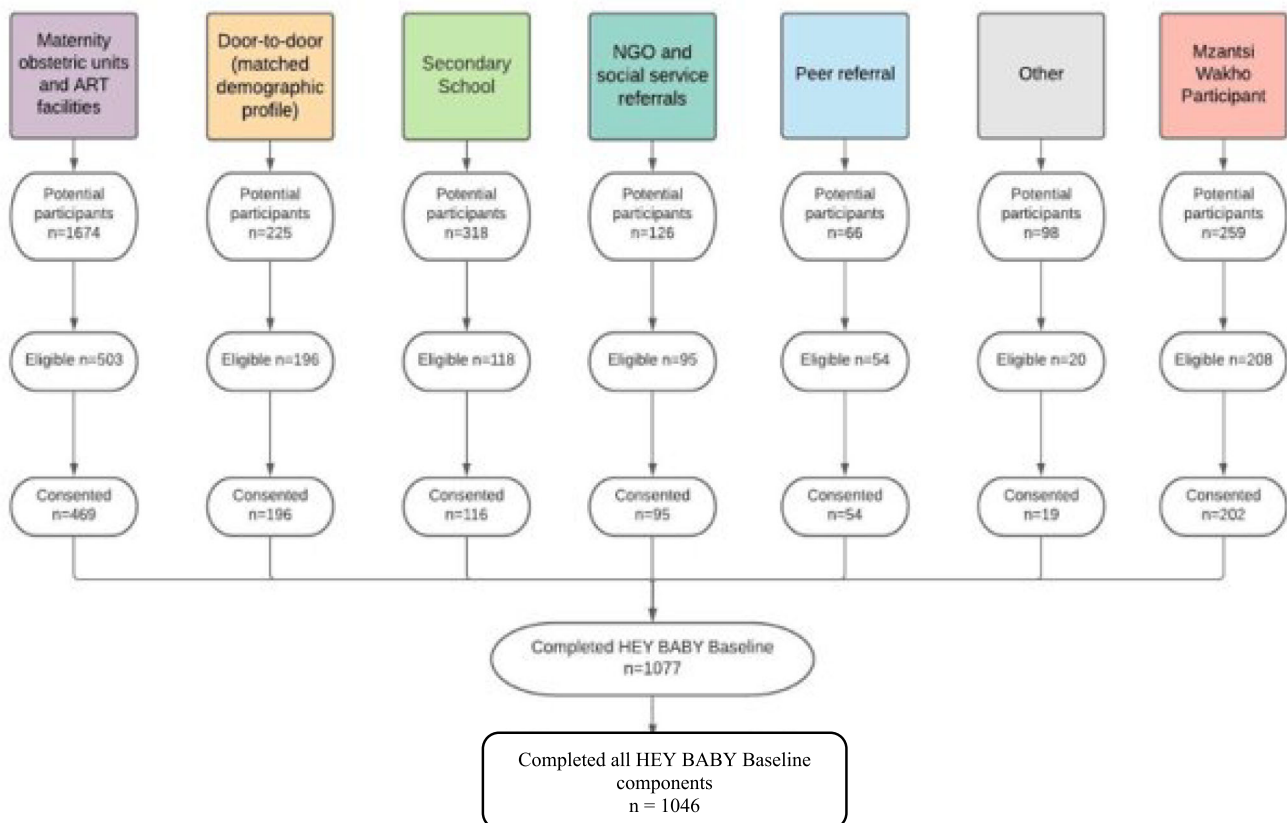

FIGURE 1 Recruitment flow diagram.

Covariates for the analyses of maternal and parenting outcomes included *Age at pregnancy of the oldest child*, *age at the time of the interview*, *HIV status*, *co-residency with a caregiver*, *rural/urban residency*, *orphanhood* (maternal or paternal), *living in informal housing* and *past-week food insecurity*, *household size*, *childcare help received from the adolescent mother's own mother or caregiver*, *multiple children per adolescent mother*, and *child disability* as measured by the WHO 'Ten Questions Screen', which detects common disabilities, including physical, mental, speech, hearing, visual and epilepsy (Durkin et al., 1995). Analyses for child outcomes controlled for *child sex*, *age*, *adolescent mothers' highest achieved grade*, *child disability* and all maternal covariates.

Confidentiality was maintained throughout the study except where participants requested help or were at risk of significant harm. Twenty-five referrals were made to health or counselling services with follow-up support. There were no monetary incentives, but all participants received a certificate, refreshments and a participant pack containing items chosen by our adolescent advisory group (e.g., washcloth, soap and crayons).

2.6 | Analyses

Adolescent mothers were eligible for inclusion in the analysis if they were pregnant within the ages of 10–19 ($n = 16$ excluded) and were the primary caregiver of a child ($n = 71$ excluded). An additional 31 participants were excluded because they showed missing values for the variables measuring childcare use ($n = 13$) and living in informal housing ($n = 18$). One hundred fifty-two participants were excluded because they had children aged younger than 4 months, which is the standard maternity leave period in South Africa (Basic Conditions of Employment Act, 1997). Our final analyses of adolescent mothers were based on 776 adolescent mothers and 837 children. Analyses for the children's outcomes were restricted to children below 68 months, in line with the valid age range for the child development assessments using within this study, resulting in 25 children being excluded based on age.

Analyses were completed in STATA 15.1 and took place in six steps. The initial steps were completed to assess frequencies and distributions of all variables. In step 1, frequencies for all outcomes and covariates were examined, disaggregated by childcare use. In step 2, we evaluated univariable associations between childcare use and all outcomes for adolescent mothers and children, respectively. In step 3, we tested for associations between childcare use and all maternal and parenting outcomes. For this, we used a multivariate generalized estimating equations multi-level analysis, which simultaneously estimated the effect of childcare use on all outcomes, controlling for a range of sociodemographic factors (the correlation matrix for all outcome variables is presented in Table 2). Using the `xtgee` command, the analyses account for within-individual clustering of the outcomes by allowing for correlated residuals. We chose an unstructured correlation structure for the model as we did not have any prespecified assumptions about the within-group correlation patterns. This approach provides an advantage compared to estimating

each outcome in a separate regression model as it corrects potentially deflated standard errors because of outcomes that are clustered within individuals. In step 4, we tested for associations of childcare use with six child outcomes. Child outcomes and mother outcomes were estimated separately for two intertwined reasons. First, we did not seek to explore hypotheses on mother–child dyads (e.g., Rasbash et al., 2009). Second, we did not aim to account for correlations between all mother and child outcomes, although child analyses accounted for maternal socio-demographic variables. In an initial exploration, we examined the within and between group variance, which showed that the clustering within the data requires a multi-level approach to the analyses. The final model used a multivariate multi-level analysis that simultaneously estimated all six child outcomes, controlling for key covariates pertaining to the mother and child (the correlation matrix for all outcome variables is presented in Table 3). Using the `meglm` command, the analyses account for two types of clustering allowing for correlated residuals. First, within-individual clustering accounts for the clustering of all outcomes within the individual. Second, family-level clustering addresses the household clustering of children of the same adolescent mother. Within these analyses, we included an interaction term between childcare use and child age as child development measures require adjustment by age to reflect developmental levels. In step 5, we estimated adjusted probabilities and marginal effects for experiencing each mother outcome, parenting outcome and child outcome, respectively, under two scenarios: not experiencing the hypothesized accelerator childcare use (UNFPA, 2022) and experiencing the hypothesized accelerator childcare use (Zulaika et al., 2022). In step 6, two sensitivity analyses were completed to supplement the robustness of the main findings.

3 | RESULTS

3.1 | Descriptive data

Table 4 shows that the average age of participating adolescent mothers was 18.40 years (SD 1.72) at the time of the interview, and their mean age at birth of first child was 16.61 years (SD 1.55). Fifty-nine adolescent mothers had given birth to two children (75% during adolescence), and three had given birth to three children at the time of the study. Nearly one third of participants lived in rural communities, and almost a quarter resided in informal housing. Just under 30% of adolescent mothers in the sample were living with HIV. About 40% of the adolescent mothers indicated being either maternally or paternally orphaned, but most adolescent mothers (91%) continued to live with a caregiver (either their biological parent or another adult) who provided some help with childcare (73.4%).

The profiles of all participating children in the study are summarized in Table 4. Proportions of boys and girls were similar. There were no gender differences in formal childcare use for boys and girls. First-born children had a mean age of 1.84 years (SD 1.24).

TABLE 1 Scales and measures.

Construct	Items, measures and instruments
Formal childcare use	We asked participants if each of their children attend any childcare services. This included childcare centres (more formal registered centres), creches (usually local small businesses in homes) or reception classes (available in or around some primary schools). Because some adolescent mothers had multiple children, a binary variable was created that captured childcare use for all children in the family with '1' (all children enrolled in formal childcare) or '0' (one or more children not enrolled in formal childcare).
Adolescent mother outcomes	
School enrolment, tertiary education or employment	Items assessed if the participant was currently enrolled in education (secondary school, college or any further education/training) or engaged in any casual or permanent work. <i>Past year grade promotion</i> was captured with one item that assessed if mothers had passed a grade in the previous year (or had completed secondary education).
Positive future ideation	A series of items, co-developed with participants, captured positive perceptions for having future good health, a satisfactory job, owning a house and stable financial situation. For each question, participants responded on a 4-point scale from 'very unlikely' to 'very likely'. The scale showed excellent internal consistency in the current sample ($\alpha = 0.95$). A final binary variable was coded, capturing 'yes' (UNFPA, 2022) if participants responded 'very likely' to all four items.
Poor mental health	A binary item was coded based on participant scores above the cut-off on any of three conditions: <i>Depression</i> within the previous 2 weeks, measured using the Child Depression Inventory short form (Kovacs, 1985). Scores of ≥ 3 (Allgaier et al., 2012; Greenland et al., 2016) were used to indicate symptomology for probable depression. The CDI-S has previously been used with adolescent populations in South Africa (Cluver et al., 2007; Sharain, 2002; Shenderovich et al., 2021; Sherr et al., 2014; Woollett et al., 2017) and shows moderate psychometric properties (CDI-S: $\alpha = 0.50$ in the current sample). <i>Anxiety</i> over the previous month was measured using the Children's Manifest Anxiety Scale—Revised (Reynolds & Richmond, 1978), reduced to 14 items through factor analysis (Boyes et al., 2013). Scores of ≥ 10 were used to indicate anxiety symptomology (Gerard & Reynolds, 1999). The RCMAS has been validated within sub-Saharan and shows good internal consistency among HIV-affected children and adolescents ($\alpha = 0.86$ in the current sample) (Boyes & Cluver, 2013). <i>Suicidality and self-harm</i> in the past month were measured using the five-item Mini International Neuropsychiatric Interview (Sheehan et al., 1997). Globally, the MINI-KID has been extensively validated and demonstrates good internal consistency ($\alpha = 0.93$ in the current sample) and good test-retest reliability (Sheehan et al., 1997; Sheehan et al., 2010). The final binary item classified participants as displaying any common poor mental health symptomology if they either reported (1) a score of ≥ 3 for probable depression or (2) scores of ≥ 10 indicating a positive screen for anxiety or (3) reported any suicidal symptoms.
Parenting outcomes	
Parenting	Parenting was assessed using an adapted version of the Parenting Young Children Scale (McEachern et al., 2012). After piloting the study questionnaire, we retained 15 items from the original measure that relate to three subscales: (UNFPA, 2022) positive parenting (e.g., 'notice and praise your child's good behaviour'); (Zulaika et al., 2022) limit-setting (e.g., 'speak calmly with your child when you were upset with him/her'); and (Thurman et al., 2006) positive discipline (e.g., 'plan ways to prevent problem behaviour'). For each question, the caregiver rated how often they were able to engage in the parenting behaviour on a 4-point scale from 'never' to 'almost daily' (McEachern et al., 2012). Each subscale was coded as a binary, with 'yes' (UNFPA, 2022) if the participant responded 'almost daily' to all items. In a study of 6–12-year-olds in South Africa, the reliability of the scale was high: supporting positive behaviour ($\alpha = 0.78$), setting limits ($\alpha = 0.79$) and proactive parenting ($\alpha = 0.79$) (Lester, 2015).
Child outcomes	
Child temperament	Child temperament was assessed using a shortened version (12 items) of the Emotionality, Activity and Shyness Temperament Questionnaire (EAS) that measures four behavioural dimensions: (1) shyness, (2) emotionality, (3) sociability and (4) activity (Buss & Plomin, 1984; Mathiesen & Tambs, 1999). Caregivers responded to three statements for each of the four domains, using a 5-point scale ranging from 1 to 5. For each subscale, binary outcomes were coded as 'yes' (UNFPA, 2022) if the participant agreed to all items, indicating if children were active, social, not shy and able to control emotions. The validity and reliability of parent reports are consistently found to be good (Masi et al., 2003).
Child illness	Based on primary caregiver self-report, a binary variable assessed if the child suffered from any serious illness in the previous year, such as pneumonia, pertussis, tuberculosis, meningitis or measles.
Child cognitive, language and motor development	Child development was assessed by trained data collectors using a scale based on the Mullen Scales of Early Learning (Mullen, 1995). These methods are described in more detail elsewhere (Steventon Roberts et al., 2022). T-scores for four developmental domains—fine motor, visual reception, expressive language and receptive language—were combined and converted to age-standardized t-scores (range 45–155). These scores were used to create a composite score of generalized developmental functioning that was

TABLE 1 (Continued)

Construct	Items, measures and instruments
	compared against a pooled estimate of means derived from nine sub-Saharan African studies (see Knerr et al., 2013). Children scoring equal to or above the pooled average ($M = 93.4$; $SD = 14.6$) were coded '1', whereas children with scores below the sample average were coded '0'.

TABLE 2 Bivariate correlations between outcome variables for adolescent mothers.

	School enrolment, tertiary education or employment	Grade promotion	Positive future ideation	Mental health symptomology	Positive parenting	Parental limit-setting	Positive discipline
School enrolment, tertiary education and employment	-						
Grade promotion	.62*	-					
Positive future ideation	.42*	.32*	-				
Mental health symptomology	-.19*	-.13	-.19*	-			
Positive parenting	.03	.09	-.09	-.09	-

Mullen child development scores	.23*	.08	-.03	.8	.21	-

*Significance level at $< .05$.

3.2 | Multivariable associations between childcare use and outcomes for adolescent mothers

Formal childcare use was associated with significantly higher odds of mothers being enrolled in secondary school, tertiary education or engaged in employment (AOR: 4.01, 95% CIs: 2.59–6.21, $p < .001$), higher odds of grade promotion (AOR: 2.08, 95% CIs: 1.42–3.05, $p < .001$) and higher odds for positive future ideation (AOR: 1.58, 95%

CIs: 1.01–2.49, $p = .047$) (Figure 2 and Table 5). Adjusted probabilities are shown in Table 6. Without formal childcare use, the adjusted probability for school enrolment, tertiary education or employment was 47%, rising to 71% with formal childcare use. Without formal childcare use, the adjusted probability for grade promotion was 53%, rising to 68% with formal childcare use. Without formal childcare use, the adjusted probability for positive future goals was 77%, rising to 84% with formal childcare use.

TABLE 4 Characteristics of adolescent mothers and children, overall and disaggregated by childcare use.

Adolescent mothers	<i>N</i> = 776% (<i>n</i>); <i>M</i> (<i>SD</i>)	<i>N</i> = 563% (<i>n</i>); <i>M</i> (<i>SD</i>)	<i>N</i> = 213% (<i>n</i>); <i>M</i> (<i>SD</i>)	<i>p</i> -value
Age at first pregnancy, years	16.61 (1.55)	16.73 (1.55)	16.30 (1.49)	<.001
Current age, years	18.40 (1.72)	18.25 (1.73)	18.82 (1.61)	<.001
Living with HIV	29.12% (226)	28.60% (161)	30.52% (65)	.600
Adolescent mother lives with their caregiver	91.11% (707)	91.30% (514)	90.61% (193)	.780
Rural residency	29.77% (231)	31.62% (178)	24.88% (53)	.078
Orphanhood (maternal or paternal)	40.46% (314)	39.43% (222)	43.19% (92)	.370
Food insecurity (3 days/past week)	9.15% (71)	10.66% (60)	5.16% (11)	.017

3.3 | Multivariable associations between childcare use and parenting for adolescent mothers

Formal childcare use was associated with better parenting behaviours on all measures: higher levels of positive parenting (AOR: 1.66, 95%

CI: 1.16–2.38, $p = .006$), better parental limit-setting (AOR: 2.00, 95% CI: 1.37–2.93, $p < .001$) and better positive discipline (AOR: 1.77, 95% CI: 1.21–2.59, $p = .003$) (Figure 2 and Table 5). Without formal childcare use, the adjusted probability for positive parenting was 34%, rising to 45% with formal childcare use. The adjusted

probability for parental limit-setting rose from 24% to 38%, and the adjusted probability for positive discipline rose from 25% to 36% (see Table 6).

3.4 | Multivariable associations between formal childcare use and outcomes for children of adolescent mothers

Formal childcare use was not associated with any child temperament measures, nor any severe illness, but it was associated with scores of the development of the children (AOR: 0.04, 95% CIs: 0.00–0.65, $p = .023$) (Figure 2 and Table 5). The interaction term between formal childcare use and child age on these scores showed that children attending childcare had better developmental scores as they grew older, compared with those who did not attend childcare (AOR: 5.04, 95% CIs: 1.59–15.96, $p = .006$). Based on these results, we calculated adjusted probabilities for the child developmental outcomes for different ages. Table 7 shows that, without formal childcare use, the adjusted probability for higher development scores was 49%, falling to 37% with formal childcare use for children aged one. There were no significant differences between the adjusted probability for child development with childcare use (36%) versus without formal childcare use (35%) at age 2. At age 3, without childcare use, the adjusted probability for higher developmental scores was 23%, rising to 35% with childcare use. At age 4, without childcare use, the adjusted probability for higher developmental scores was 14%, rising to 33% with childcare use. At age 5, without formal childcare use, the adjusted probability for higher development scores was 7%, rising to 32% with childcare use. At age 6, without childcare use, the adjusted probability for higher developmental scores was 4%, rising to 31% with childcare use.²

4 | DISCUSSION

In 2020, a report by the World Bank found that access to quality childcare has the potential to unlock pathways out of poverty, build human capital amongst women and their children and increase inclusive growth at a national level. It identified deeply uneven access in childcare provision and recommended that a crucial component of the COVID recovery will be smart public finance investments to support the childcare industry (Devercelli & Beaton-Day, 2020). However, the report identified almost no evidence focused on adolescent parents.

This study provides some of the first evidence from the Global South of associations between access to formal childcare and maternal, parenting and child outcomes for adolescent mothers. It finds substantial positive associations for adolescent mothers of having children in formal childcare, particularly on maternal access to education and employment, grade promotion and positive future ideation. This is crucial for adolescent health and human capital outcomes: Improving educational access and positive future ideation are predictive of improved lifetime employment, earnings, better birth spacing,

reduced intimate partner violence, HIV incidence and better child health (Abramsky et al., 2011; Balaj et al., 2021; Gadoth & Heymann, 2020; Schultz, 2002; Vandemoortele & Delamonica, 2000).

This study also finds positive associations of access to childcare across all measured parenting outcomes: positive parenting, parental limit-setting and positive discipline. Improved early parenting is associated with better outcomes for children, with higher school readiness, executive function, lifetime earnings (Shafiq et al., 2018) and lower behaviour problems (Black et al., 2017; Richter et al., 2017). In particular, parental warmth and positive discipline/limit setting are identified with reduced rates of family violence against children, and protective parent-child relationships (Knerr et al., 2013). Access to stable childcare could affect parenting via reduced parenting stress (Abidin, 1992; Crnic et al., 2005; Deater-Deckard, 1998), even though there is mixed evidence on this relationship (Craig & Churchill, 2018). Young mothers from our Teen Advisory Group confirmed the importance of childcare for their capabilities of education, employment and future aspirations.

The study did not find differences on maternal mental health, or on child temperament. This reflects mixed evidence on adult mothers and their children but may also highlight important contextual challenges. Adolescent motherhood (particularly out of marriage) remains highly stigmatized globally (Hall et al., 2018), and studies in the region report high levels of emotional distress experienced by adolescent mothers (Mutahi et al., 2022). Young mothers in our Teen Advisory Group echoed the concern that young mothers likely require additional support to cope with early parenthood, frequently co-occurring with rejection from families and the child's father, and with postpartum mental health challenges. They also identified that formal childcare led to both improved child behaviour (through teachers) and potential behaviour challenges (through contact with other children)—reflecting wider literature on school and child behaviour in low-income areas.

However, our findings show that children attending childcare have better cognitive, language and motor outcomes as they age, compared with children not attending childcare. This is of crucial importance for a group highly vulnerable to poor educational outcomes. Systematic reviews of child outcomes identify that quality of childcare (e.g., stimulation of children) may determine whether there are beneficial impacts on child health and development (National Institute of Child Health and Human Development Early Child Care Research Network & Duncan, 2003). Even in the very deprived setting of South Africa's Eastern Cape, where childcare services are most often in local homes and lacking qualified staff, we see positive outcomes, but this also suggests the added value and potential for building capacity and resources in early childhood development within childcare settings (Wolf et al., 2019). In our study, adolescent mothers reported the average cost for formal childcare to be 154 South African Rand per month, which converts to about \$9, rendering it a low-cost option to improve outcomes for adolescents and children. Previous research showed that, across 73 developing countries, increasing preschool enrolment to 50% in a single year could increase a countries' productivity by \$33 billion across those children's lifetimes (Engle et al., 2011). Evidence-based multi-sectoral packages,

which could include access to childcare, for pregnant adolescents and adolescent mothers are a crucial step in supporting their school progression and HIV risk reduction, strengthening positive future outlook and supporting the healthy development for the next generation (Cluver et al., 2022; Jochim et al., *Forthcoming*). There are important future areas for research in understanding associations of different kinds of childcare settings with child and adolescent mother outcomes and differential impacts by age of children. Following others' recommendation on childcare in Sub-Saharan Africa (Bakibinga & Matanda, 2022), future research should also further assess the current obstacles of adolescent mothers to access childcare and interrogate how to better connect young mothers to existing childcare services. We need more rigorous research on the effective ingredients for support packages serving adolescent mothers and comprehensive evidence syntheses with multiple stakeholders to start developing pilot packages that can be tested in communities (Kelly et al., 2023). Additional costing analyses are necessary to encourage the allocation of financial resources from the government towards quality early care that lead to a move away from informal centres and overburdening families with childcare cost. Our correlational findings also warrant further testing of causal relationships between formal childcare use and adolescent and child outcomes through randomized controlled trials and investigations into the pathways towards important development outcomes. These explorations should include how to effectively measure quality service provisions and identify specific objectives for parents, households, communities and child-level outcomes.

This study has several limitations. First, we used cross-sectional data that limit the capacity to determine causality and, for some of the identified relationships, reverse causality is possible. For example, mothers who are well supported to return to school or remain employed after the pregnancy might be more likely to use childcare. However, analyses controlled for factors likely to influence childcare access, maternal and child outcomes, such as poverty, informal housing, maternal age, HIV status, household composition, number of children and child disability. Second, there is always risk of social desirability bias, which may have affected self-reported parenting by adolescent mothers (although this was unlikely to differ by childcare access), and some of the items on parenting may have been less applicable to very young children. We attempted to reduce these limitations through pre-piloting our questionnaire items with the Teen Advisory Group and highly empathetic, very well trained, local interviewers, many of whom had been young parents themselves. We conducted sensitivity analyses restricted to children over 12 months old, finding similar associations despite reduced sample size. Lastly, the generalizability to other low- and middle-income country settings remains unknown, and further testing is clearly required, although the socio-economic conditions and limited service access in the study area may be representative of conditions across Southern Africa (see Tables 8 and 9).

The study also has key strengths. To our knowledge, it is the first large-scale study of adolescent mothers and their children in the Global South and included independent cognitive, language and motor development testing of their children. The study took place in a real-

TABLE 8 Sensitivity analyses: Multivariable associations between childcare use and outcomes for mothers with children who are above the age of 1 year ($n = 507$).

	Adjusted odds ratio	Std. err.	z	P > z	[95% Conf. Interval]	
School enrolment and employment	3.63	.88	5.31	<.001	2.25	5.83
Grade promotion	2.25	.48	3.81	<.001	1.48	3.43
Positive future ideation	1.71	.43	2.14	.033	1.05	2.79
Mental health symptomology	1.50	.48	1.37	.170	.84	2.69
Positive parenting	1.46	.29	1.90	.057	.99	2.17
Parental limit-setting	1.67	.35	2.41	.016	1.10	2.52
Positive discipline	1.46	.31	1.80	.072	.96	2.21

Note: The table below shows consistency with our main results, indicating that formal childcare use was associated with significantly higher odds of maternal school enrolment, tertiary education or employment (AOR: 3.63, 95% CIs: 2.25–5.83, $p < .001$), higher odds for grade promotion (AOR: 2.25, 95% CIs: 1.48–3.43, $p < .001$), and higher odds for positive future goals (AOR: 1.71, 95% CIs: 1.05–2.79, $p = .033$). Formal childcare use was also associated with higher odds for better parental limit-setting (AOR: 1.67, 95% CIs: 1.10–2.52, $p = .02$), and similar trends (but not reaching significance) for positive parenting (AOR: 1.46, 95% CIs: 0.99–2.17, $p = .057$) and increased positive discipline (AOR: 1.46, 95% CIs: 0.96–2.21, $p = .07$).

TABLE 9 Sensitivity analyses: Multivariable associations between childcare use and outcomes for children who are above the age of 1 year ($n = 588$).

	Adjusted odds ratio	Std. err.	z	P > z	[95% Conf. Interval]	
Child temperament—emotionality	.72	.30	−0.78	.436	.32	1.63
Child temperament—shyness	.50	.28	−1.22	.221	.17	1.50
Child temperament—activity	1.17	.41	0.46	.648	.59	2.34
Child temperament—sociability	1.30	.34	1.03	.305	.78	2.16
Any severe illness, past year	.76	.57	−0.25	.725	.18	3.33
Mullen child development scores, above pooled average from the region	1.73	1.04	0.92	.345	.53	5.62

Note: For the children, the table below shows results for all child outcomes for participants whose children were above 1 year. The results reflect previous analyses, showing no significant differences for any child temperament scales or child illness. These supplementary analyses did not show a significant interaction between formal childcare use and child age for child development once we excluded children below 1 year.

world, highly deprived setting, allowing an understanding of associations of childcare access even in a context where this was likely to be lower quality than that provided in randomized trials. This study used analysis techniques that allowed simultaneous modelling of correlated outcomes within mothers, such as educational success and positive future ideation, and children, such as illness and child development.

Quality formal childcare provision is emerging as a global need, with the International Labor Organization estimating that 800 million children under 6 years old need access to care (Addati et al., 2018). UN Women highlight the potential ‘triple dividend’ of increasing female labour force participation, improving child outcomes and creating jobs in the care sector (UN WOMEN, 2015). Particularly vulnerable adolescents and young women, such as those working in the informal economy and adolescent mothers, might share a particular need for childcare support (Horwood et al., 2019). The COVID pandemic—where billions of families struggled to manage without childcare access—has highlighted its importance in the world economy (Gromada et al., 2020). Our findings suggest that adolescent mothers and their children are an essential group to consider in the increasing

demand for access to childcare. Improving access to childcare services represents an important intervention that needs to be further explored with different methodologies, considering causal impact (Richardson et al., 2018). In regions like Sub-Saharan Africa, they are a major population group, experiencing severe intergenerational disadvantage and future risk. Providing access to reliable, subsidized quality childcare may be an essential ingredient in improving health and human capital for adolescent mothers and their children.

ACKNOWLEDGEMENTS

The authors are grateful to the young mothers and their families, the data collection team and partner organizations that supported the research process, as well as St Anne’s College Nursery, Oxford. We are also grateful to Mark Orkin, William Rudgard, Siyanai Zhou, James Baker, Anna Carlqvist and the wider Accelerate Hub team for engaging with the conceptual thinking surrounding this research and valuable discussions and comments on the manuscript. Special thanks to Chelsea Coakley and Hlokoma Mangqalaza for collating feedback from young mothers about the study results and to Leah de Jager for supporting the graphics and illustrations of this work.

CONFLICT OF INTEREST STATEMENT

The authors declare no conflict of interest.

DATA SHARING AND DATA AVAILABILITY STATEMENT

Prospective users, policymakers/government agencies/researchers (internal/external) will be required to contact the study team to discuss and plan the use of data. Research data will be available on request subject to participant consent and having completed all necessary documentation. All data requests should be sent to the Principal Investigator.

ETHICS APPROVAL STATEMENT

Ethical approval was provided by the University of Oxford and the University of Cape Town (R48876/RE001; R48876/RE002; HREC REF: 226/2017) and the Eastern Cape Provincial Departments of Health, Basic Education, and Social Development.

PARENT CONSENT STATEMENT

Voluntary informed consent was sought from adolescents who were above the age of 18 and assent was provided by underage participants in addition to consent from their adult caregiver.

ENDNOTES

¹ A scoping review was led by two co-authors. Searches were conducted on Google Scholar and PubMed during January–March 2022. The search strategy aimed to identify any research or program report examining the effect of a range of formal childcare services (e.g., universal childcare, day care, creche, playschool and center-based day care) on any adolescent mother outcomes including mental health, school enrolment, future ideation and aspirations, health, household income and parental employment. Publications were screened based on relevance of the title and reference lists of relevant publications were additionally screened.

² Parenting Young Children Scale includes items that might not apply to very young children, and some children may enter childcare later (i.e., after 12 months). Therefore, we conducted sensitivity analyses for a subsample of participants whose children are above 1 year old. The results indicate consistent results.
