RATING SYSTEMS AND INCREASED HETEROGENEITY IN FIRM PERFORMANCE: EVIDENCE FROM THE NEW YORK CITY RESTAURANT INDUSTRY, 1994-2013

Research summary: We investigate the extent to which the increasing availability of ratings information has affected heterogeneity in firm performance and, if so, what market segments are responsible for these changes. A unique dataset was constructed with restricted-access government revenue data to examine these questions in the context of the New York City restaurant industry between 1994-2013. We find that firms serving tourist and expensive price point market segments experienced increasing sales discrepancies as a function of rating differentials when ratings information became more easily accessible with the advent of online rating platforms. These findings depict how the prevalence of online rating systems have shaped competition and value capture, thus providing insight into the determinants of firm performance heterogeneity.

Managerial summary: We examine the extent to which increasing availability of ratings information has affected firm performance by estimating changes in comparative sales between New York City restaurants between 1994-2013. Analyses indicates that increased access to ratings information during this period had a considerable effect on comparative sales for firms serving certain market segments: firms serving tourist and the expensive price point market segments experienced increased sales discrepancies as a function of their rating differences after online rating platforms proliferated. These results provide insights into other industries where access to evaluations and rating systems have also increased. This work suggests that online ratings have affected how firms compete and capture value, and managers have opportunities to use rating systems to their advantage.

Introduction

Supported by advances in digital and mobile technologies, easy access to online expert and crowd-sourced ratings information has altered how individuals make consumption choices, as well as the range of alternative options that buyers consider when making purchases (Bapna, 2017; Blank, 2007; Chen & Xie, 2005, 2008; Chevalier & Mayzlin, 2006; Dellarocas, 2003; Lu & Rui, 2017; Luca, 2016; Zhu & Zhang, 2010). In turn, the aggregate impact of individual consumers' decisions has the potential to dramatically affect market-level outcomes, such as comparative firm performance (Luca, 2016; Salganik, Dodds, & Watts, 2006; Evans, 2008). Accordingly, managers have noted the strategic importance of ratings, rankings, and evaluations in crafting their business strategy and customer relationship management procedures (Baka, 2016; Dellarocas, 2006; Ifrach et al., 2019; Mayzlin, Dover, & Chevalier, 2014). Hence, understanding how the dramatic

expansion of rating systems has systematically affected firm performance is a pressing issue for both strategic management scholars and practitioners.

The extent to which the increased availability and use of ratings information has systematically affected the comparative performance of competing firms in an industry remains an open question. If all relevant differences among firms and their product offerings were widely and easily known with perfect reliability, buyers could assess competing firms and their product offerings on their own. The opaqueness of market interfaces, however, complicates the assessment of comparability among firms, creating the opportunity for third parties (e.g., critics, analysts, policymakers, regulators) to provide independent assessments (Cattani et al., 2018). Third-party ratings, rankings, and other forms of categorization are important because they define which firms compete in specific markets, as well as which firms are comparable to others on various dimensions they deem important (e.g., Cattani, Porac, & Thomas, 2017; Kennedy, 2008; White, 2004). Historically, detailed information about perceptions of quality has not been easy to ascertain and measure. The advent of the Internet, however, made some of this information, particularly about mean consumer ratings, far more easily accessible (Lu & Rui, 2017). Due to advances in information technologies, rating systems have become instrumental in the identification and construction of 'better' options for millions of people around the world every day. Correspondingly, buyer option-sets and subsequent decisions can be influenced by one summary parameter of quality like in Rosen's (1981) classic economics of superstars (see also Sauder & Espeland, 2009; Orlikowski & Scott, 2014).

A potential consequence of the proliferation of digital ratings, therefore, is that third party ratings increasingly influence comparative firm performance. This should not be taken for granted writ large, however, as research suggests that differences among rating systems, and even

fraudulent ratings, can engender evaluative ambiguities or obfuscate core characteristics of the evaluated offerings (Cattani et al., 2018; Chatterji et al., 2016; Fleischer, 2009). Moreover, in imperfectly competitive markets, the choice parameters of buyers are multi-dimensional (Gergaud, Storchmann, & Veradi, 2015; Sands et al., 2021), and this dimensionality varies by market segment (Belton & Stewart, 2002; Zionts & Wallenius, 1976). Target consumers' need for more and better information likely varies across markets based on prior or vicarious experience or the expected value of the consumption choice. Firms also vary in their capacity and inclination to react strategically to rating systems, which may further exacerbate performance differences (Espeland & Sauder, 2007; Orlikowski & Scott, 2014). Thus, at the market level, it is an open question in the literature whether and how ubiquitous ratings may have heterogeneous effects on firms operating in different market segments.

In this paper, we examine how the increasing availability of ratings information made possible by the Internet and associated technologies affected the comparative performance of firms. Our empirical setting is the New York City (NYC) restaurant industry from 1994-2013, a period of study that purposefully envelopes the advent and diffusion of a host of online restaurant rating platforms such as *Yelp, TripAdvisor, and OpenTable*. To establish the set of restaurants we sample, we collected, digitized, coded, and matched time-varying NYC restaurant ratings data from print versions of the *Zagat Survey*, an early pioneer in the crowd-sourced restaurant review industry that preceded the advent and expansion period of online reviews; this allows us to study changes over the time period that envelopes the advent and proliferation of restaurant ratings information. We then matched this information about NYC restaurants to performance data we derived from restricted-access administrative information about firms' financial outcomes. In

bringing these data together, we developed a unique panel dataset containing two decades of NYC restaurant-year ratings observations that include granular measures of actual restaurant sales.

We operationalize competition as a network of competitor-dyad observations based on the presupposition that competition is relational and is best modeled as such (Cattani et al., 2018; Hawley, 1950; Hannan & Freeman, 1977; White, 2004). Our dataset consists of approximately 4.7 million competitor pair (or dyad) years, which uniquely afford us the opportunity to investigate changes in relative sales across the NYC restaurant industry over two decades. Indeed, one of the advantages of the relational modeling approach we develop in this paper is that it helps us understand competitive dynamics in markets where firms compete and differentiate along many characteristics (e.g., Athey et al., 2018; Cattani et al., 2017, 2018; Lavie, 2021; Sands et al., 2021; Thatchenkery & Katila, 2021). We also use geospatial data to contextualize competitive differences by market segments that have comparatively less local information and, hence, may have a greater need for ratings information when assessing options (Besbes & Scarsini, 2018). Thus, we can investigate how more easily accessible ratings information changed competitors' sales differentials across segments of the market that may vary in their need for, and use of, such information without applying overly restrictive identifying assumptions.

Our empirical analyses yield several results about how digital ratings affect relative firm performance. As a baseline, we observe a positive relationship between favorable ratings and sales. However, we do not find evidence that comparative sales disparities have changed in the post-online restaurant rating platform entry/expansion period for NYC restaurants. Our results do, however, suggest that disparities in sales have significantly increased as a function of differences in ratings in the post-online period for restaurants located in areas that cater to tourists. A dyadic fixed-effects model is employed to define scope conditions concerning how this effect is driven,

in large part, by restaurants in the most expensive price point tier. These findings are consistent with our theoretical framework in which ratings information is particularly useful and important when firms are serving market segments containing buyers with less local information and for those firms that cater to consumers who are seeking more expensive cultural/experiential goods.

Our research provides some of the first evidence concerning the extent to which the accessibility of ratings information has shaped comparative firm performance across an entire market, relative to a period when such information was far less readily available. Our access to restricted government data including private firm sales information allowed us to investigate directly how the entry and expansion of online ratings have led to sales disparities between competing firms. Accordingly, we provide a market-level view of how the enhanced accessibility of rating systems has affected the distribution of value between firms and across different market segments. This focus explores and eventually establishes a tight linkage between ratings information and fundamental strategic outcomes. Additionally, by leveraging archival and interview material, our work helps to contextualize both the performance effects of rating systems and the managerial experiences around the entry and rapid expansion of digital ratings. In doing so, this research shows which market segments are most impacted by these changes, thus contributing to a growing scholarly dialogue that has underscored the complex roles that third-party evaluation plays in markets.

The Empirical Setting: The New York City Restaurant Industry

Our empirical goal in this paper is to examine the relationship between ratings information and comparative firms' sales in the NYC restaurant industry between 1994 and 2013. For the purposes of external validity, this is a compelling strategic research site because the multiplicity of dimensions along which restaurants are (dis)similar reflects an intense competitive environment

(e.g., Cattani et al., 2018). While social evaluations have been a feature of the industry since its inception, tastes and opinions are far from monolithic in a place like NYC (Davis, 2009; Hauck-Lawson & Deutsch, 2009). Thus, this empirical setting provides us with rich contextual details that allow us to take a nuanced look at the expansion of rating systems. Moreover, the restaurant industry is culturally, socially, and economically vital to the country, and to NYC in particular. In terms of economic importance, the United States restaurant industry generates approximately \$800 billion dollar in total sales, approximately 4% of Gross Domestic Product (GDP) (National Restaurant Association, 2019). The restaurant and foodservice industry also employed more than twelve million Americans in 2018 (Bureau of Labor Statistics. 2018). In NYC, restaurants account for approximately 300,000 jobs (New York State Department of Labor, 2015). The restaurant industry has long been a hotbed for female, minority, and immigrant entrepreneurship, making this a particularly important setting for those interested in business ownership within these groups (National Restaurant Association, 2016).

Restaurants also shape the economic, social, and cultural vitality of geographic areas. Where, how, and what we eat also signifies our taste, culture, and identity, as well as how they change in time and vary between groups (Johnston & Bauman, 2007; Rao, Monin, & Durand, 2003; 2005). Accordingly, research has also demonstrated that housing prices are correlated with both the quantity and quality of restaurants in a neighborhood (Kuang. 2017). Some have thus argued that restaurants can be a catalyst or predictor of urban development, change, and gentrification (e.g., Carroll & Torfason, 2011; Glaeser, Kim, & Luca, 2017; Zukin, Lindeman, & Hurson, 2015; Turco, 2023). Urbanist Jane Jacobs (1961) noted long ago that residents are quick to refer to local restaurants as a sign of the vitality and appeal of their communities. Consequently, substantial scholarly research has focused on food and restaurants to study culture, creativity,

categories, boundaries, work, and the attribution of valuation and meaning (Blank, 2007; Dupin & Wezel, 2023; Fine, 2008; Carrol & Wheaton, 2009; Demetry, 2013; Kovács, Carroll, & Lehman, 2014; Lane, 2014; Leschziner, 2015; Goldberg, Hannan, & Kovács, 2016; Opazo, 2016). As famed food critic Anthony Bourdain expressed it, "Food is everything we are" (Schulz, 2010).

Information, Technology, and Ratings: A Brief History of Restaurant Rating Systems

While information technologies have only recently altered the ease with which ratings can be accessed, hungry patrons have nevertheless been searching for information about what and where to eat for a long time. The *L'Almanach des gourmands*, published in 19th century France, is often cited as the first codified review of restaurants (Blank, 2007). *Michelin*, a French tire company founded by brothers André and Edouard, published its well-known restaurant guides starting in 1900 based on the idea that cars using their tires would be used to travel to destination restaurants. *The Michelin Guide*, however, would not cover NYC for another 105 years. The first *New York Times* restaurant review was published in 1859, but restaurant-specific reviews only became a regular feature in 1962 (Wells, 2018). *The New York Times* has employed eleven head restaurant critics since then (Parker, 2016). Other NYC media outlets have followed with restaurant critics of their own. However, the limited ability of media-employed individual critics to cover large and dynamic markets meant that only a very small subset of local restaurants ever received a published review.

The scalability challenge of professional critics,² along with the attendant market opportunity for quality assessments, was first addressed in the 1980s by Nina and Tim Zagat who pioneered a 'crowd-based' approach to restaurant ratings with their *Zagat Survey* guidebooks. Drawing initially on their circle of gourmet friends, the Zagats created a survey to rate restaurants on separate dimensions of quality including food, service, and décor. As the NYC culinary

revolution created a market of 'foodies' starting in the early 1980s (McNamee, 2012; Mitchell, 2009), *Zagat* expanded its reach and coverage. By the 1990s, their coverage encompassed more than 1,000 restaurants (Weber, 1995).³ Indeed, *Zagat* was regarded as, "a closely followed report card for chefs and restaurateurs" who recognized that ratings had the potential to shape consumer behavior (Fabricant, 1997, p. F4).

Responding to changes in the broader technological landscape, *Zagat* initially launched an online version of their eponymous guide in 1999, but they placed their ratings behind a paywall. The strategic choice to implement a paywall system likely limited *Zagat's* diffusion and growth; however, it protected book sales, which remained the company's primary source of revenue. Cost and availability of access, along with a comparatively limited range of coverage for even survey-based rating systems, left an opening for new entrants to come into the space as advances in information technologies took hold more widely (see Hitt & Tambe, 2007 for a study on migration to broadband and content consumption).

The digital platform *Yelp* was founded in 2004; it quickly became one of the dominant sources of online restaurant information utilizing crowd-sourced consumer ratings. *Yelp* went from an average of 0.3 million unique visitors per month in 2005 to 5.7 million in 2007 to 26 million in 2009. Hence, the period of *Yelp's* market entry and growth are reasonably construed as the period in which accessibility and use of information about the ratings of restaurants increased exponentially. It should be emphasized that even these platforms do not and cannot cover all NYC restaurants. Every rating system entails selected samples, with the degree of selection more extreme in expert-based ratings because professional critics have only so much capacity. Notwithstanding substantial differences in coverage and form, the ratings for specific restaurants are correlated (Apple, 1998; Silver, 2014). Indeed, the biggest change to the industry over the past

few decades has not been the content itself, but rather the expanded coverage of, and ease of access to, this content.

Market segment heterogeneity in the use of ratings information

To the extent that ratings information affects buyer decision-making, it should follow that the expansion of access to rating systems has the potential to shape the relative performance of firms. While all consumers may realize some benefit of access to ratings information, the discriminating value of ratings information should be greater for buyers who have comparatively less first-hand experience or information about 'local' (in either physical or conceptual space) product offerings. For these interested buyers, accessibility of ratings information should prove more influential when their decision is perceived as more economically or socially important. Hence, how rating systems affect relative firm performance may vary by market segment.

In the NYC restaurant market, tourists represent the prototypical consumer segment that has comparatively less local information and, thus, a greater need for ratings information.⁴ Local residents, by contrast, have other sources of information about restaurants—be it first-hand experience, word-of-mouth, or from coverage by local media sources—that make ratings information relatively less useful. Tourists, nevertheless, represent a significant segment of restaurant-goers, and one of the main expenditures of tourists is restaurant dining (Cohen, 1984; Urry, 1990). In 2016, for example, tourists accounted for 24% of all dollars spent in restaurants in NYC (see Appendix). Given tourists' lack of local information about restaurants, we expect firms that serve this market segment to be more strongly impacted by ratings information.

Just as with the tourist segment (compared to locals), the relative value of ratings information should be greater for those consumers who are making particularly expensive dining decisions compared to those seeking less costly dining options. This follows because potential

buyers, on average, have less first-hand knowledge about expensive offerings, and they pay more attention to ratings when they anticipate high expenditure. Moreover, the initial decision to select from a consideration set of expensive restaurants may be driven by an underlying social desire to impress others (e.g., a date or a business meeting), in which case dining at a better or the best option is entirely the point of consumption (Bagwell & Bernheim, 1996; Leibenstein, 1950). We should, therefore, expect to observe even greater sales performance implications from ratings information for firms serving within the high price segment of the market.

Ultimately, we theorize that there is a relationship between the entry and expansion of rating systems access and increased heterogeneity in firm performance. We expect this relationship to be stronger for firms operating in market segments where their consumers have limited sources of local information. Such market segments include areas with a high concentration of tourists and for restaurants operating at the expensive price point. Thus, the core empirical investigations driving this research are whether: (1) the increasing ease with which these ratings can be accessed due to the Internet and advances in information technology results in greater disparity in competing businesses' sales, and (2) this disparity is exacerbated in market segments that serve buyers who require more or different type of information to facilitate their decision-making. This reasoning implies the following three hypotheses concerning the advent and expansion of digital rating systems within the NYC restaurant industry and their performance effects:

Hypothesis 1: As the availability of information concerning the comparative rating difference of competitors increases, the relative disparity in sales increases between competitors.

Hypothesis 2: As the availability of information concerning the comparative rating difference of competitors increases, the relative disparity in sales increases between competitors within tourist-focused market segments.

Hypothesis 3: As the availability of information concerning the comparative rating difference of competitors increases, the relative disparity in sales increases between competitors within tourist-focused market segments at the expensive price-point.

Analytical Challenges and Strategy Modeling N-dimensional Competition

Our analytical objective is to determine to what extent the advent and increasing usage of ratings information has exacerbated or mitigated disparities in sales between competitors in the NYC restaurant industry. This begs the question: who is a competitor? This is amongst the fundamental questions in the literature that concerns competitive strategy and imperfect competition (Cattani et al., 2017; Robinson, 1933; Rothschild & Stiglitz, 1976). A market is imperfectly competitive to the extent that producers have *n* dimensions along with they can differentiate themselves from others. In such markets many different competitors can be regarded as substitutes for a given purpose depending on how the choice-set is defined. Any judgment of substitutability depends on a host of context-specific particulars. Consider in our setting, for example, a Thai restaurant and a steakhouse. Are they competitors? Assume, further, they are either on the same block or across town from one another. What if they are similarly priced and have similar quality ratings? Could one consider two restaurants with different cuisines in different NYC boroughs (separated by an hour commute) substitutes? Variability in the answers to these questions highlights the difficulty in designating two entities as competitors in a multidimensional market.

Despite the number of dimensions along which restaurants can compete, business owners must make strategic decisions that consider, to varying degrees, their competition however defined. Consumers and critics, in turn, form their evaluations and make consumption decisions with reference to some set of (perhaps implicit) comparable options that may be similar on some dimensions and differ on, or are ambiguous with respect to, others (Askin & Mauskapf, 2017; Bian et al., 2022; Cattani et al., 2018; Fleischer, 2009; Greenberg, 2021; Sands et al., 2021; Zuckerman,

1999). When a customer considers what to eat for lunch, for example, distance to work may be a plausible 'filter' she imposes as far as she prefers to minimize delivery time and cost. She may also have in mind a relative price range, and a floor for product quality. With these parameters defined, she may, however, be open to a variety of options that reflect combinations of these parameters on any given day. This example is for one discrete consumption choice, which has been the topic of considerable study going back to McFadden (Manski, 2001), but is not the focus here. Rather, the number of dimensions along which one might consider options as substitutes over the course of a day, let alone a year, is greater—thus, revealing the limitations of a matching-approach when considering daily, monthly, or yearly differentials.

Given the conceptual challenges described above, we begin with a risk set in which all restaurants in New York City theoretically compete, and we then put structure around this question with the rich data collected and described in the subsequent section. Provided the relational nature of competition, we conceptualize competition here as a matrix, M, with a risk-set of $(\frac{N(N-1)}{2})_t$ competitive dyads. As such, we will hypothesize that the aggregation of consumers' choices indicates substantial cross-firm sales implications. This reflects that the "action of all on the common supply give rise to a *reciprocal relation* between each unit and all others, if only from the fact that what one gets reduces by that the amount what the others can obtain" (Hawley, 1950, p. 202, emphasis added). Importantly, this approach does not require *a priori* answers to the question of 'who is a competitor?' which would demand a great deal of the researcher and for which sound science is lacking. Instead, the dyadic approach makes relatively limited assumptions in treating every dyad pair as a competitive interaction of equal weight, even if this may induce some noise and be computationally intensive. Pragmatically, since we obtained government permission to utilize an extensive amount of restricted-access data, this affords us the ability to

overcome the limitations of, and need for, imposing match-based constraints because we do not need to pre-specify sets of competitors.

Data

Our data collection and compilation process began with a United States Census Bureau Federal Statistical Research Data Center (RDC) application for access to restricted-access administrative data for private firms' total value of sales information. The proposal specified the research question, the required administrative variables and their intended use, as well as the researcher-provided data (e.g., restaurant ratings and characteristics) we would need to merge to run analyses specified in the proposal.⁶

For the ratings information, we purchased historical editions of Zagat guides for NYC for the study window. NYC was Zagat's first and largest market, thus providing the largest number of observations for the longest time-series, which covered both the pre- and post-online rating system proliferation periods. We were able to find the long out-of-print Zagat volumes through an extensive search at used bookstores and other online resale outlets such as eBay and Amazon. Given the unstandardized physical specifications of Zagat guides (3.8 x 8.5 inches—which was considered a feature that would allow them to be more conveniently held in a pocket), we deconstructed the guide page-by-page and then scanned them. Scanned pages were then converted into an editable format using OCR software. Algorithmic and human coding ensued to fix conversion errors, particularly those associated with the unique characters and symbols used in Zagat. Thus, for each non-chain Zagat rated-restaurant-year entry we created a data point capturing its name, address, the brief (often snarky) description of the restaurant that was curated by a Zagat editor to represent the essence of the crowd-based ratings and qualitative reviews; the average price for a meal with drink and tip; the cuisine category; and quantitative ratings for food,

décor, and service on a thirty-point scale. We linked these observations over time to construct our panel dataset of NYC restaurants and their by-year *Zagat* ratings (1994-2013). Given inconsistencies in naming conventions across our various data sources, the next steps of our dataset construction necessitated cleaning and matching of observations with usable data. Following extensive data cleaning, processing, and matching to our two-decade panel of restaurants with corresponding ratings information, we conducted descriptive and graphical analyses to explore variable distributions. This stage informed the construction of all variables described in subsequent sections.

Measures

Outcome

The outcome measure used in this study is the urban CPI-deflated difference in sales between restaurants i and j in year t. These data are restricted access government data from the BR consisting of detailed private businesses information. Our outcome variable thus represents yearly sales performance for private firms.

Predictors

Ratings. To measure restaurant ratings, we use the Zagat survey ratings data. The size of the survey respondents that contributed to the ratings scale estimate grew increasingly larger throughout the years. 9 Zagat volumes were historically released in the final quarter of the previous calendar year (i.e., the 2006 NYC Zagat Survey went on sale in October 2005). Hence, the reviews used here are lagged slightly more than one calendar year and are updated (time-varying) yearly. We created an overall restaurant rating based on the mean of a restaurant's food, décor, and service scores (Cronbach $\alpha = 0.84^{10}$), and then calculated the difference between restaurant i's and j's rating in year t-1. As noted above, we also find that Zagat ratings measures are strongly correlated

with Yelp ratings, which is in line with evidence from related prior work related to this topic. For example, Kovács, Carroll, and Lehman (2014) found that Zagat ratings measures are strongly correlated with Yelp ratings, and within restaurant ratings are very highly correlated year-over-year. To further corroborate this finding, we linked all available New York Times critic ratings by restaurant-year to Zagat ratings between 1994 and 2013 and found the two to be correlated (r = 0.45, exact p-value = 0.0000). Likewise, using 2016 data, we linked Yelp and TripAdvisor NYC area ratings, and found that the pair-wise correlation was r = 0.52 (exact p-value = 0.0000).

What all these ratings correlations imply is that, while each platform may differ in its taxonomic structure and business logic and are therefore not analytically interchangeable, they tend to agree about the underlying quality of restaurants—something that media coverage of NYC restaurant ratings has noted as well (e.g., Apple, 1998; Silver, 2014). However, the assumption that these ratings do converge should not be taken for granted since research has documented other empirical settings in which this is not the case (e.g., Chatterji et al., 2016). Nevertheless, our analyses suggest that the rating platforms in the New York City restaurant industry are generally consistent in a way that allows for the use of Zagat ratings as a proxy for the ratings given by, or which might have been given by, other platforms if they had existed for a longer period. As the New York Times noted in their 1998 coverage of Zagat's 20th anniversary, "the top restaurants chosen by Zagat's amateurs do not vary markedly from those chosen by the pros, whether critics, food writers or restaurateurs. That is not surprising, since the pros influence the amateurs to start with" (Apple, 1998, p.F1). Put differently, if restaurant quality is considered a partially socially constructed latent variable, then the various rating platforms should be correlated. This is precisely what we, and others, have observed in analyzing these data. For the purposes of our empirical investigation, therefore, we use Zagat ratings as the proxy measure of quality from these sources,

which crucially allows us to have an observable source of ratings information for the era prior to digital rating platform entry and expansion.

Tourist market segment. Tourists are a significant force in the restaurant industry, accounting for a quarter of the \$9.1 billion in sales volume at food and drinking establishments in 2016 (Gonzalez-Rivera, 2018). In an ideal analytical setup, a researcher would be able to perfectly measure directly, over time, the proportion of a restaurant's customers in terms of where they live along with other demographic information. Absent this information, we extrapolate those areas frequented by tourists by identifying areas with high prevalence of hotels relative to city residents. We took several steps to ensure construct validity (see Appendix for additional detail). First, we tabulated the twenty largest hotels by available beds in NYC by zip code. Every single one of the largest hotels is located in a zip code denoted here as a tourist neighborhood. Because these hotels tend to be double-occupancy, and Manhattan's occupancy rate has hovered between 75% and 85%, the number of hotel rooms provides a reasonable lower bound of the number of tourists in an area at a given time. Second, using population data from the US Census, we calculated the ratio of residents in the zip codes denoted as tourist versus those in areas typically regarded as residential. This coding scheme provides a reasonable if indirect means of designating places in NYC as tourist-concentrated. This procedure ultimately generated a tourist area designation that encompasses many of the great tourist sites of NYC, including: the Broadway Theater District, Times Square, the southern part of Central Park, and the World Trade Center/Freedom Tower. Thus, from a face-validity perspective, we observe that popular characterizations of NYC tourist sites correspond to our coding schema (e.g., Lee, 2003).

<u>Exogenous information shock: Online restaurant review market entry and expansion.</u> Yelp was founded in 2004, and quickly became the leader in online restaurant ratings and reviews (see

also Luca (2016)). At roughly the same time, *TripAdvisor* expanded in the restaurant evaluation market, as did *OpenTable*, even though their primary business had been and remains reservation coordination (see Appendix). Hence, we code a dummy variable that distinguishes the pre- and post-online restaurant rating platform entry period around this time. The functional form implied by our theoretical argument noted above need not be discrete in nature. That is, information in this setting is not a discrete shock but rather a continuous treatment, as noted in the earlier discussion of rating systems. Moreover, *Yelp* expanded to new international markets in 2010, including countries such as France, Germany, and Spain, which constitute important source countries for NYC tourism and would have allowed those consumers to more effectively access and use restaurant ratings when traveling to NYC. Hence, we specify a second binary variable indicating the post-2010 online restaurant rating platform expansion period, as it is plausible that the ratings effect became more pronounced over time. Finally, we created a continuous variable in which all years prior to 2005 are coded as 0 (i.e., pre-online restaurant rating platform entry), 2005 == 1, 2006 == 2, ..., 2013 == 9.

Interactions to test hypotheses. A baseline test of the impact of ratings information employs a two-way interaction between the (lagged) ratings scale differential and the respective variable indicating: (a) the online restaurant ratings platform market entry (2005+) period, (b) the expansion period (2010+), or (c) the continuous measure. The second hypothesis is tested with a three-way interaction between location (both restaurants in an area with a high tourist concentration), the (lagged) ratings scale differential, and the respective variable indicating the online restaurant rating platform market entry period (2005+), its expansion period (2010+), or the continuous measure denoting greater online restaurant rating platform adoption and usage. Finally, the third hypothesis adds an indicator variable denoting that both restaurants are in the highest price-tier (\$\$\$\$),

corresponding to the "very expensive" price point designated by *Zagat*. We employ a four-way interaction as it provides a statistical test of the relevant differences in quality by market segments (*tourist* by *expensive*) in a specific period.

Controls

<u>Competitor geo-distance.</u> In theory, substitutability should decrease with distance (Rosen, 1981; Athey et al., 2018). Hence, we measure geodetic distance between all dyadic pairs of restaurants. We also specify binary measures denoting that they are both in the same borough (Manhattan) where the density of competitors is greatest. Supplemental analyses not presented with the main text include zip or tract code fixed-effects and yield similar estimates.

Competitor cuisine category overlap. A dimension for potential substitutability in this setting is cuisine type. The models presented below use the Zagat cuisine classification. For estimation and disclosure/confidentiality reasons, we combined sub-forms of cuisines together (e.g., Northern and Southern Italian). In total, we created eighteen cuisine categories, as well as a summary measure to denote category similarity or difference. In models not presented here for disclosure reasons, we operationalized two competitors as occupying the same category with varying levels of specificity. In the most granular model (>80 categories), we defined two restaurants as similar in cuisine category if and only if the two competitors' classifications were identical. The results of that exercise yielded similar results to those presented in the main tables.

Notable owners and top-lists. To account for managerial effects, we coded a binary variable from Zagat that designates whether a restaurant had a notable owner insofar as it was owned by a celebrity chef or had a renowned restaurateur associated with it. Having a celebrity chef in the ownership team may also indicate the restaurant has operational and marketing skills or advantages such as cheaper/free publicity that are likely to increase sales. Indeed, a notable owner sets the

blueprint for a restaurant (Baron, Hannan, & Berton, 1999) and is likely to garner attention from critics and the popular press. Thus, this variable also helps us account for some of the idiosyncratic advantages that derive from celebrity in competitive markets (Rindova, Pollock, & Hayward, 2006).

In each Zagat guide there are lists that provide sets of top-rated restaurants within particular categories or use-cases. These lists include being a "noteworthy newcomer" or "trendy." Many of these dimensions are not measured directly in surveys, leaving them up to editorial discretion. In turn, there is a positive correlation between notable ownership and being on a top list, net of quality. As with the notable owner variable, this measure is time invariant for theoretical and practical reasons. Theoretically, if status effects are durable, being on a top list should have a lasting effect. Pragmatically, many of these lists do not change that markedly in time, and those that do often have too few cases for robust estimation and disclosure review thresholds. It should be noted that quality ratings, notable ownership, and being on a top list are correlated, albeit modestly, ranging from r=0.22 to r=0.36 (p<.0001).

<u>Price.</u> The total value of sales for restaurants is a function of two primary parameters: the number of customers served and the average sale price per customer. Price is also both a signal, and endogenous reflection, of underlying product quality (Roberts, Khaire, & Rider, 2011). Additionally, Luca and Reshef (2021) demonstrate restaurants receive less favorable consumer ratings when their prices are higher. Accordingly, we control for the ratio of competitor i's and j's prices, where price reflects the average sale price per customer for dinner including one drink and tip. This average estimate is not for a specific meal (e.g., popular item, tasting menu, prix fixe), but rather constitutes an overall average meal cost that is derived from survey responses from all consumers rating a particular restaurant in a given year. Note that for the purposes of our

hypothesis testing, we denote the most expensive price-tier in subsequent tables as "\$\$\$\$," which reflects the market stratifications provided by *Zagat* and later *Yelp*. All price figures are deflated using the urban CPI for cross-year comparability.

<u>Time trend effects.</u> We also include linear time trend effects to account for general trends in competitive differences or market conditions, and as a basis of distinguishing the period effect triple-differences that are of interest here. In analyses not reported here, we also estimated models with polynomial time trend effects, which had no bearing on the period effect results presented below. Simple descriptive statistics permissible by disclosure rules are included in Table 1.¹¹

Insert Table 1 about here

Analytical Model

We tested our hypotheses by specifying OLS models predicting Urban CPI-deflated sales differentials between competitors i and j as:

 Y_i - $Y_j = \beta_1(Rating\ scale_i - Rating\ scale_j)_{t-1} + \beta_2(Notable\ owner_{i\neq j}) + \beta_3(Top\ list_{i\neq j}) + \beta_4(Post-online\ rating\ platform\ entry/expansion\ period) + \beta_5(Rating\ scale_i - Rating\ scale_j)_{t-1}$ * $(Post-online\ rating\ platform\ entry/expansion\ period) + \beta_6(X) + \theta + \mathcal{E}_{i,i,ij}$

In this model, $[Y_i - Y_j]_t = [X_{in} - X_{jn}]_t = 0$ is the special case of perfect substitution insofar as there are no differences between two competitors. This model is used to establish a baseline concerning the period effects. The first and second hypotheses rely on three-way and four-way interactions, respectively, that build on this specification. X refers to the matrix of controls described above, and θ represents a time trend to help clarify interpretation of the period effects of interest by excluding alternative interpretations concerning secular trends or economic conditions. Given the matrix of 4.7 million dyads employed in this study to model potential competitors, observations are not independent, and half the possible dyads are dropped given they are

symmetric duplicates. Due to government restricted-access data disclosure requirements, exact cell sizes cannot be disclosed; actual numbers are, thus, rounded.

Based on our analyses of intra-class correlations, we use standard errors that are multi-way clustered to account for the non-independence of observations along *i* and *j* and *ij* dimensions (Cameron et al., 2011). We develop models progressively, adding the interaction terms to tests the hypotheses after building intuition with simpler models. For robustness, we also specify the final model in a fixed-effects (within dyad) framework. This model accounts for all dyadic competitor time-invariant characteristics including brand equity and comparative starting positions (or imprints) that may explain sales differentials.

Presentation of Findings

Insert Table 2 about here

Baseline rating difference effects and tests of Hypothesis 1. Table 2 presents OLS regression coefficients from the repeated cross-sectional dyadic competitor matrix. Following recent calls (e.g., Benjamin et al. 2018) and to facilitate easier assessment on the part of the reader, we present exact p-values to four digits in parentheses, where p-values are based on multi-way clustered standard errors. All reported estimates are in \$1,000s of urban CPI-deflated dollars. As variables are normally distributed and the outcome is comparative sales, the coefficients can be interpreted as the disparity in (deflated) sales associated with a one-unit increase in a predictor.

Models one through ten estimate baseline rating difference effects on firm sales disparities (Hypothesis 1). The first model includes only the coefficient for the comparative restaurant rating differential as it predicts differences in competitors' sales. The estimate is \$333,000, with an exact *p*-value of 0.0000. As a point of reference, a standard deviation in the scale is slightly greater than four; this implies a one standard deviation rating difference corresponds to more than \$1,300,000

in comparative sales. This result is the performance consequence of a basic rating disparity, which captures potential quality differences between restaurants and the publicization of these differences. We note that this is an upper bound estimate, which decreases in subsequent models with the inclusion of additional controls. Model two adds the variable denoting that competitor i but not j was at some point featured on a top list. (The inverse of this measure, as well as the offdiagonal values, are not informative and thus omitted.) This coefficient is large, implying a sales differential of \$1,866,000 net of the difference in rating (exact p-value = 0.0013). Model three, in turn, adds an intersection effect (Goodman, 2002; Greenberg, 2014; Greenberg & Mollick, 2017) denoting that competitor i but not j has a notable owner. As above, the inverse and off-diagonal values are omitted. The estimate is \$1,517,000 (exact p-value = 0.0000) in comparative revenue, net of the rating difference and being featured on a top list. Including this measure reduces the top list estimate, and it reduces the size of the comparative rating difference estimate. This is not surprising as the three measures are correlated, as noted above. Notable owners offer a restaurant experience that is more highly rated. But that is only a portion of the producer effect observed here. In our fifty-five interviews with restaurateurs and review of historical material, we observe that notable owners often have an advantage via cheaper marketing activities. For example, a new restaurant by a notable owner is often featured in the media on lists such as 'hot new restaurants' and 'tough tickets' even before the crowd or experts have rendered a rating.

Model four includes extensive controls including geodesic dyadic distance between competitors, cuisine category similarity, borough, comparative average meal price of i/j, and a time trend. It also introduces control variables for both restaurants being co-located in a tourist area and the dummy variable denoting the post-online platform entry (2005+) period. Neither of these coefficients are statistically significant at conventional levels. However, with their addition

and the other controls, the rating scale difference effect is reduced by more than half compared to Model one to \$134,800 (exact p-value = 0.0000). If we interpret this more modest figure with respect to a one standard deviation difference in ratings as we did earlier, this implies there is an approximately \$550,000 comparative sales differential. Model five, in turn, repeats this exercise with the dummy variable denoting the restaurant rating platform expansion period (2010+); that is, the period when Yelp dramatically grew its domestic and international user base, thereby diffusing restaurant ratings information further. In both models, the online restaurant rating platform entry or expansion coefficients are not statistically significant at conventional levels. When coupled with a control for the time trend, this suggests that sales differentials are not explained simply by time, secular shifts, or time-varying and broader economic conditions. These models also shed light on the competitive dynamics that characterize the industry. For example, net of controls, restaurants founded by notable owners earn approximately \$1.5 million more than restaurants without a notable owner. This owner effect is so large that restaurants with notable owners with a 50th percentile rating earn more than restaurants with a 75th percentile rating without a notable owner. Indeed, a restaurant that is not owned by a notable restaurateur would need a rating equal to or greater than the 91st percentile rating to be statistically indistinguishable in sales relative to a restaurant with a notable owner at the 50th percentile of the rating scale. The evidence also suggests that restaurants featured on a top list earn, on average, approximately \$1.32 million more than those that are never featured on a top list, net of controls.

In Model six, we include an interaction term between the comparative rating difference and the online restaurant rating platform entry period starting in 2005. Model seven includes an interaction term between the comparative rating and online restaurant rating platform expansion period starting in 2010. The interaction term displays a small effect size (b= -\$51,610; exact p-

value = 0.0996), and the expansion period estimate also displays a small point estimate with a 95% confidence interval that encompasses zero (b= -\$46,490; exact p-value = 0.1617). Hence, we do not observe a reliable market-level sales effect that has changed significantly over time, and we do not find evidence to support Hypothesis 1.

In Model eight, we introduce an interaction between the comparative rating difference and the measure denoting that both competitors are located in a tourist area. The estimate for this variable is \$111,800 (exact p-value = 0.0036). It suggests that ignoring the period of online rating platforms entry or expansion, rating differentials matter more in a context where consumers have less local information about eating options, on average. This estimate provides preliminary support for Hypothesis 2. However, it is only a partial test. Models nine and ten add the interaction terms for the rating scale differential and the post-online platform entry (2005+) and expansion (2010+) periods with the variable denoting tourist markets. Including these measures does not substantially alter the effect observed in the tourist area segment and helps build intuition for subsequent models.

Insert Table 3 and Figure 1 about here

Tests of Hypotheses 2 and 3. Models eleven and twelve in Table 3 provide direct tests of Hypothesis 2. Model eleven includes a three-way interaction for i and j's rating difference when they both were located in a tourist area in the post online restaurant rating platform period (2005+). These effects are also plotted in Figure 1. Model twelve, in turn, uses the online restaurant rating platform expansion (2010+) period measure instead. In both models, the moderation effect is strongly evident. The three-way interaction effect in Model eleven (2005+) is \$119,000 (exact p-value=0.0086), and in Model 12 (2010+) it is \$132,500 (exact p-value = 0.0070). These estimates imply that the ratings information effect is getting larger with time in market segments where consumers' external information is limited. Thus, the models presented in Table 3 and in Figure 1

provide support for Hypothesis 2. As our theorizing indicated, however, there is reason to believe that other market sub-segments may also have a greater need for, and reliance on, ratings information.

Table 4 and Figure 2 about here

In Table 4, we turn to this matter as a test of our third hypothesis. These models entail a four-way interaction between the tourist market, competitor rating differential, the period effects denoting the online restaurant rating platform entry period, and an intersection effect denoting that both competitors were in the most expensive price-tier (\$\$\$\$).¹² Model thirteen in Table 4 is similar in form (a repeated cross-sectional competitor matrix) as our previous models, and it indicates a large interaction term of \$406,100 (exact p-value = 0.0036). To facilitate interpretation of these results, we linearly graphed the coefficients of the equation in Figure 2. The Y-axis reflects deflated sales differentials. Because of the larger magnitude and range of the rating differences on competitors' sales differentials, it is worth noting that the scale is denominated in \$200,000. The x-axis represents the difference in the competitors' ratings. Given the range and scale of values, and to make the graphic intuitive, the top graph in Figure 2 illustrates disparities for restaurants located in tourist areas in the pre- and post-online restaurant rating platform entry period separated by price tier. The graphic illustrates the substantial returns to better ratings for those competitors in tourist areas offering the highest priced products in the post-online platform entry/expansion (2005+) period, while the pattern of effects in non-tourist areas appears to be far less definitive. With respect to slope comparisons, the pre- and post-\$\$\$ slopes are statistically different in tourist areas for quality scale values above one standard deviation. In non-tourist areas the same comparison does not indicate a reliably different slope.

Model fourteen provides a test of robustness specifically designed to address empirical concerns related to un-observables by including competitor-dyad fixed effects. The four-way interaction effect in this model is \$205,400 (exact *p*-value = 0.0003). An advantage of this model is that it absorbs dyadic-specific factors such as initial advantages and imprints that may not vary in time, and therefore provides a particularly powerful basis of comparison.¹³ Indeed, this models the situation where two restaurants compete with each other before the online rating platform market entry or expansion periods, as well as after as a function of these period differences and rating disparities updated in time. Ultimately, these results are consistent with those presented in the repeated cross-sectional pooled competitor dyad models.

Supplementary analyses and contextualizing our investigation. To help us better understand underlying changes in the market during this time and how such changes may affect our interpretation of the results, we also examined a complete restaurant-year panel for all restaurants listed in the 1994-2013 Zagat guidebooks. We note that this supplemental dataset was constructed completely outside the RDC for the purposes of these post hoc analyses, which allows us to discuss years/market segments without disclosure concerns related to the comingling of confidential data. Analyses of these data at the firm-year level underscore some other notable changes that took place during our two decades of study. We observe that the number of restaurants covered in the Zagat guidebooks had increased along with the growth in the population of NYC, and mean restaurant ratings have steadily inflated: 21% of restaurants had a Zagat rating of less than 15 (out of 30) from 1994 to 1999, 11% 2000-2004, 8% 2005-2009, and 4% 2010-2013 (see Appendix). While ratings inflation has been identified elsewhere in the literature, some of it has been attributed to buyer behavioral changes (e.g., Filippas, Horton, & Golden, 2022), but this may also be consistent with work such as Chatterji and Toffel (2010) who find differences in firm

responses to positive and negative ratings. We should consider it plausible that the reduction in low restaurant ratings may also be driven by supply-side responses wherein restaurateurs seek to avoid unfavorable ratings. Indeed, our analyses provide some evidence that favorable ratings have been positively correlated with restaurant survival throughout our period of study. It is plausible that rating-exit relationships have changed after online ratings became available, but we do not clearly observe any distinct effects on survival between market segments over time.¹⁴

These supplementary analyses offer some general insight into the developments in the restaurant evaluation industry during this time, as well as inform additional robustness checks. Additional models were thus estimated to account for possible alternative interpretations of the patterns observed here. As noted with our main analyses, we controlled for time effects in various ways to account for secular trends and alternative period effects. Other specifications yield similar results and enhance our confidence in the primary approach. For example, in an alternative model to those presented in Table 4, we allow all post-online platform entry/expansion years to vary linearly. These analyses indicate that the effect is increasing in the post-online platform entry/expansion period by \$24,130 per year from 2005 to 2013 (exact *p*-value= 0.0025), which is in line with our main results. Consistent with these findings, a NYC restaurateur we interviewed reflected on the increased importance of receiving and maintaining favorable ratings, stating that: "It's not about ego. That's how you make money."

Discussion

Tracing the origins of performance heterogeneity among firms has been the central topic in strategy research (Barney, 1986; Nelson, 1991; Peteraf, 1993; Porter, 1980; 1985), and the growing importance of third-party rating systems across a variety of industries raises new questions as to their influence in shaping firm performance. To this end, our in-depth analysis of rating systems

elucidates "the role that third-parties can play in influencing value creation and capture in product markets" (Cattani et al., 2017, p. 84). By leveraging special access to government restricted data, we examined the extent to which increasing availability of ratings information, facilitated by the entry and expansion of online restaurant rating platforms, led to greater disparity levels in sales among restaurants in NYC between 1994-2013.

Our work provides important context-specific evidence concerning the much larger question about whether the Internet has exacerbated sales performance disparities between competitors as consumers are more easily informed about others' perceptions as to what are better, or the best, options. Explaining how and why the impact of rating systems varies across firms within the same industry is amongst the key questions we face in an ever increasingly digitized world of ratings, rankings, and evaluation (Blank, 2007; Bowers & Prato, 2019; Chu & Noh, 2019; Espeland & Sauder, 2007; Rindova et al., 2018; Sauder & Espeland, 2009; Sauder & Lancaster, 2006). As we show in this paper, unpacking these differences entails delineating conditions under which such differential impact can be observed. Our results indicate that the effects of rating systems on how firms capture value may be contingent on the particulars of a given market segment. Prior research examining topics related to ratings, rankings, and evaluations has focused on other cultural settings, including beer and wine (e.g., Benjamin & Podolny, 1999; Frake, 2016), books (e.g., Kovács & Sharkey, 2014; Wang, Zhang, & Hann, 2018), and movies (e.g., Ferriani et al., 2009; Olson & Waguespack, 2020; Hsu, 2006). Science, particularly the natural sciences, and the legal context, have also proven fruitful research sites (e.g., Sauder & Lancaster, 2006; Sauder & Espeland, 2009). So, while we examined within-industry differences in market segments and show that they matter, cross-industry comparisons may also suggest other differences in how firms are able to capture value. This boundary condition concerning to what degree ratings information

affects market outcomes may depend on the extent to which a setting exhibits the following features: (near) zero marginal costs, endogeneity in evaluation, a high correlation between producer status and product quality and pricing, and the range of parameters that are plausible differentiators (see also Lamont, 2012; Zuckerman, 2012). Provided restaurant multi-dimensionality corresponds to frictions in buyer beliefs about substitutability, this paper's setting may yield conservative estimates of ratings effects compared to other markets. In contexts with non-zero marginal costs, there is a ceiling on the extent to which one firm can capture all available rents, and contexts with a lower correlation between producer status and quality may exhibit less competitive disparities as ratings information increases.

The extent to which rating systems shape organizational behavior by leading managers to adjust to match ratings criteria (e.g., Favaron, Di Stefano, & Durand, 2022; Pollock, D'Adderio, & Williams, 2018; Sauder & Espeland, 2006; Sauder & Lancaster, 2006; Sharkey & Bromley, 2015) suggests that the expansion of rating systems can both provide opportunities for differentiation and also lead to isomorphism. Collectively, these considerations reflect important issues for future research as they will allow us to develop a better understanding of the impact of rating systems on strategic management across settings. Likewise, the fact that fake ratings have become increasingly prevalent as the variety of rating platforms has continued to expand raises new questions about the legitimacy of ratings and how managers should respond (e.g., Anderson & Magruder, 2012; Cattani et al., 2018; Luca, 2016; Luca & Zervas, 2016; see also Guynn & Chang, 2012; Streitfeld, 2012). Ensuring a favorable client experience is increasingly regarded as vital by organizations engaging in electronic commerce as it correlates with ratings, and sales by implication. In the context of restaurants, we find that notable restaurateurs were correlated with higher ratings, placement on top lists, and greater comparative sales, seemingly corroborating the

idea that management matters on several margins. In many firms, this entails functional roles devoted entirely to managing social media, customer, support, and online ratings (Proserpio & Zervas, 2017). Indeed, some of the restaurateurs we interviewed indicated that in weekly staff meetings they often discuss customer reviews as a basis for gauging in real time various facets of their performance. One NYC restauranteur emphasized, "we talk about it every Tuesday morning." Another one of the chef-owners that we spoke to, who was even particularly adamant that she did not want her vision for the restaurant to be distracted by ratings, still went on to underscore that: "My front-of-the-house general manager's responsibility is to read those things." Others also stressed the need to reach out to dissatisfied customers who might give particularly bad ratings and pen especially caustic reviews—a feature that Yelp introduced in 2009 (Cain Miller, 2009, p. B8; see also Wang, Wezel, & Forgues, 2016). Others discussed the need to consider customer product experience by offering frills or promotions to early users to garner high ratings (Kuksov & Xie, 2010). Firms that do not have this social marketing savvy and relational management capabilities are likely at a competitive disadvantage as the digital interface between the firm and consumers becomes more dynamic.

Another managerial implication of this study is that as information on competitors becomes more granular—and recommendation systems incorporate this information to make it more easily communicated to those with less local information such as tourists—it is plausible that information technology may lessen sales disparities amongst competitors by enabling greater horizontal differentiation at the business-level, which is consistent with work suggesting long-tail effects (e.g., Brynjolfsson, Hu, & Smith, 2010; Fleder & Hosanagar, 2009). This, in turn, demands that managers make strategic positioning decisions and engage in meaning-making to capture value. Likewise, there may be upstream consequences of persistent heterogeneity in firm performance

within particular market segments as this can impact the economic well-being of the value-chains and communities in which these firms operate. Wilmers (2017), for example, studies how consumers for higher end goods drive disparities in employees' pay. Our paper considers a similar question as it pertains to disparities in firm sales, which, in turn, is a key lever that leads to disparities in employee hiring and pay. In conjunction, such possibilities highlight that the supply-side effects of third-party evaluation have been, thus far, notably absent from the literature in strategic management.

Conclusion

Our research helps to build upon existing theory and extend our knowledge about the strategic impact of the rise of rating systems. We build on previous work related to ratings, showing with unique quantitative data, how ratings drive substantial differences in competitors' sales performance; how this effect is shaped by enormous changes in information technology; and which market segments are particularly susceptible to information effects (i.e., heterogeneous effects) that explain increasing sales disparities for a specific subset of competitors. Second, this research focuses on a specific market over time, rather than just at the product-level, thereby showing directly how information technology effects can shape the competitive landscape for both firms and entire markets, in addition to specific products that prior research has considered (e.g., Li & Hitt, 2008; Oestreicher-Singer & Sundararajan, 2012). Importantly, this work provides estimates of competitive implications of one of the biggest informational shocks in recent years: the widespread diffusion of online ratings information.

We show that to understand the importance and impact of ratings information effects one must consider the nature of competition within particular market segments. In general, we find little evidence that across the entire market online restaurant rating platforms increased disparities

in sales between NYC restaurants, even though we do see a baseline positive relationship between favorable ratings and sales. It stands to reason that buyers have always preferred higher rated options, and, in turn, higher rated restaurants have greater sales. However, for firms that compete in those market segments where their customers have a greater need for ratings information due to less local information or more substantial expenditures, there is considerable evidence that sales disparities have increased dramatically in those periods with easier access to ratings information.

Figure 1. Competitor Sales Differentials as a Function of Rating Differences by Tourist Area Market Segment in the Pre- and Post-Online Rating Platform Entry/Expansion Period

Note. Y-axis represents Urban CPI-deflated competitor sales differentials in 1,000s of US Dollars. Rating scale difference denotes difference in competitors' Zagat rating scale. Estimates from regression Model 11 in Table 3 with 3-way interaction that includes the post-online platform entry/expansion entry (2005+) period. The estimates used in the above figure includes all the controls noted in text for Model 11. Source material US RDC restricted access administrative data and Zagat volumes 1994-2013.

Figure 2. Competitor Sales Differentials as a Function of Rating Differences by Tourist Area and Price Tier Market Segments in the Pre- and Post-Online Rating Platform Entry/Expansion Period

Note. Y-axis represents Urban CPI-deflated competitor sales differentials in 1,000s of US Dollars. Rating difference denotes difference in competitors' Zagat rating. Top figure derived from estimates from regression Model 14 in Table 4 with 4-way interaction that includes the post-online platform entry/expansion entry (2005+) period and price tier dummy variable denoting that both competitors are in the \$\$\$\$ tier, or not. Source material US RDC restricted access administrative data and Zagat volumes 1994-2013.

_

¹ In what seems like prescient use of language, a 1989 *New York Times* article about *Zagat* described how: "Many restaurateurs believe the Zagats (Nina and Tim) perform a valuable service by giving *democratic assessments* of eating places. Others, however, question the method" [emphasis added] (Hall, 1989, p. C1).

² In August of 2016, *The New York Times* ceased its coverage of restaurants (and other cultural institutions) in the Tri-State area outside NYC. Though mourned by many, this business decision reflected the constraints related to the cost of expert-based ratings and the limits such a system imposes on scalability. Even if an expert reviewer eats out five times per week and dines at a restaurant multiple times before submitting a review, as *New York Times* critic Pete Wells does (Parker, 2016), there is a clear and costly ceiling on the number of ratings and reviews that can be written by such experts.

³ Zagat focused on full-service restaurants. It was never designed to cover all chain restaurants, bars, bodegas, food stands/trucks, or pop-ups in the same way that decentralized digital platforms like *Yelp* would later be able to do more effectively (see Appendix).

⁴ For an alternative approach concerning those who frequent a restaurant see Cai, Chen, and Fang (2009). These authors used an experiment coupled with a post-treatment survey of those experimental participants to determine how observable ranking information of dishes influenced consumer ordering behavior. They then surveyed the experimental participants and interacted the experimental treatment variables with an indicator for frequenting the restaurant at least six times. The interaction term in their LPM was -0.0004 (S.E. = 0.0002), with a constant value of 0.043. This suggests a slight (in substantive terms) moderation effect for inferred familiarity on experimentally manipulated consumption choices in the presence of ranking information.

- ⁷ Zagat's focus on non-chain restaurants in NYC remained throughout our period of investigation, which never exceeded 14% of its by-year coverage. There was an expansion of its chain coverage over time alongside its stable expansion of coverage. Nevertheless, chain restaurants have been relatively less common in NYC compared to other places in the country. Note also that Luca's (2016) work on *Yelp* ratings in Washington State focuses explicitly on the effect of ratings access in areas where chain restaurants are/were more prevalent, which offers detailed consideration of these issues.
- ⁸ Other than the challenges obtaining administrative approval for disclosure and standard issues around matching, Haltiwanger et al. (2017) point out a variety of challenges in using these sorts of government restricted data, such as missing observations or inconsistent year-over-year coding. The BR revenue data have limitations that would pose challenges in different settings, but our interest in non-chain restaurants make it an ideal candidate for this project (see Haltiwanger et al., 2017, p.17). While it was a labour-intensive process, we were able to overcome some of the potentially inherent data limitations by linking observations by-hand to ensure that we only kept observations with reliable data. Our sample, then, can plausibly reflect a bias to firms with reliable tax filings. One issue related to dataset construction, which was specific to our setting, was the fact that NYC restaurant names are often the incorporated business name. That is, 'Firm A' does business as (DBA) 'Restaurant Z.' The fact that they are misaligned makes matching *Zagat* data to IRS data difficult, even with address and phone number information. However, we were able to overcome this issue by leveraging crosswalk data.
- ⁹ Note that in *Zagat*, the number of restaurant-specific reviews is not observable. However, prior research suggests that quality ratings have an appreciable effect (e.g., Lu et al., 2013; Luca, 2016; Wu et al., 2015).
- These ratings are so highly correlated that including each rating separately induces multicollinearity. We thus obtain similar results if we select just one dimension. Our approach seeks to provide a more comprehensive assessment by including these different dimensions in an overall restaurant rating.
- ¹¹ See also the material available in the Appendix for a variety of disclosable descriptive and summary measures.
- ¹² As indicated earlier, for the purposes of confidentiality and disclosure requirement we report only models with multi-way interactions. We did, however, receive government approval for qualitative disclosure to confirm that subsample analyses provide results that are consistent, with respect to direction and significance of our variables of interest, with those presented in the main tables.
- ¹³ These models include a very large number of fixed effects. We also estimated this model conditional on price tier (\$\$\$\$) with a 3-way interaction. Results are consistent with those presented here. Again, government disclosure rules make related sub-sample analysis presentation complicated. However, employing the full sample with interaction terms to test predictions also allows for a simpler basis of calculating tests of differences.
- ¹⁴ Supplemental survival analyses consider not only the correlation between a given firm's ratings and their likelihood of exit holding constant the market-level mean rating, but also the relative changes in ratings for individual firms, to include the restaurant's ratings compared to their own average lifetime rating and their year-over-year rating change. See Appendix.

⁵ For government disclosure review purposes only, we also estimated models at the firm-level. Results were consistent with those presented below. However, such a firm-level analysis does not allow for the calculation of similarity and difference metrics that are vital given the network conceptualization of competition used here.

⁶ We note in advance of our analyses that there are restrictions imposed on the use and reporting of the government data used here. First, the researcher is circumscribed by her ex-ante proposal. Second, there are strict rules pertaining to where and what data can be analysed. Third, there are strict data disclosure rules and requirements (see https://web.archive.org/web/20170211213119/https://www.census.gov/content/dam/Census/programs-surveys/sipp/methodology/RDCDisclosureRequestMemo.pdf)..

RATING SYSTEMS AND INCREASED HETEROGENEITY IN FIRM PERFORMANCE: EVIDENCE FROM THE NEW YORK CITY RESTAURANT INDUSTRY, 1994-2013

ONLINE SUPPLEMENTARY MATERIAL

TABLE OF CONTENTS

<u>Item</u>	Description/Purpose
I. Tables	
Table A1	Timeline and summary of key events in Zagat history to provide context for rating system development and underlying data
Table A2	List of top 20 hotels in New York City by number of rooms to support location coding of tourist areas
Table A3	Ratio of hotel rooms to population in select zip codes to illustrate and substantiate location coding (along with Table A2)
Table A4	Cox proportional hazards model survival analyses of restaurant rating and changes in firm exit by year to examine how rating system entry/expansion has influenced exit likelihood (see also Figures A23-A29)
Table A5	Time-varying coefficient Cox proportional hazards model survival analyses of restaurant rating and changes in firm exit by year to examine how ratings expansion has influenced exit likelihood (see also Figures A23-A29)
Table A6	Cox proportional hazards model survival analyses of restaurant rating deviation from mean and changes in firm exit by year to examine how relative changes have occurred over time (see also Figures A23-A29)
Table A7	Time-varying coefficient Cox proportional hazards model survival analyses of restaurant rating deviation from mean and changes in firm exit by year to examine how relative changes have occurred over time (see also Figures A23-A29)
Table A8	Cox proportional hazards model analyses of restaurant rating year-over-year difference and changes in firm exit by year to see how within-restaurant changes are driving exit (see also Figures A23-A29)
Table A9	Time-varying coefficient Cox proportional hazards model analyses of restaurant rating year-over-year difference and changes in firm exit by year to see how within-restaurant changes are driving exit (see also Figures A23-A29)
Table A10	Historical qualitative material of reactions to rating systems to provide context for supply-side ratings reactions and managerial salience

APPENDIX TABLES

Table A1. Timeline, Key Events, and Metrics for Zagat

Year	Event/Milestone	Description
1963	Founders meet	Tim Zagat and Nina Safronoff get to know each other in a Yale Law School study group
1979	Beginning of company	Tim and Nina host dinner parties for "foodies." Guest complain about newspaper restaurant critics. The Zagats decide to poll friends. No NYC publisher interested in their business pitch.
1980	First survey	100 - 200 surveys from "amateur critics" rate 100 restaurants on food, décor, service, cleanliness (later dropped), and cost, which is complied into a newsletter-type document and distributed
1983	Book Publication	Zagat survey first published in book form
1983	Sales Growth	~7,500 copies sold
1984	Sales Growth	~15,000 copies sold
1985	Sales Growth	~40,000 copies sold
1986	Sales Growth	~100,000 copies sold
1987	Sales Growth	~150,000 copies sold
	Tim focuses on Zagat	Tim quits job and starts to focus on Zagat exclusively
1988	Sales Growth	~200,000 copies sold
1989	Coverage	868 restaurants rated by 3,500 amateur critics. \$9.95 per guide
1990	Nina joins Zagat full-time	Nina moves to Zagat full-time in order to support expanding operations
1993	Sales	~400,000 copies sold
1995	Coverage	Zagat guidebook coverages reaches 1500 NYC restaurants
1997	Sales	~500,000 copies sold
1999	Online site launched	Online site launch behind paywall in May
2000	Raised VC	One round of VC, \$31 million (led by General Atlantic; included Kleiner Perkins and Allen & Co.) for 25% stake
2003	Geographic expansion	70 different city guides published
2004	Sued for defamation	Sued by Lucky Cheng's for defamation associated with a negative review. Plaintiff argued review caused a 35% reduction in income. The judge dismissed the case
2006	Coverage	Zagat guidebook coverages reaches 2000 NYC restaurants
2007	Size of company	120 employees in NYC office; 180 contractors abroad
	Sales Growth	~650,000 copies sold
2008	Zagat for sale	Reports suggest asking price ~\$200 million. Goldman Sachs hired to handle sale
2010	Online presence	Nielsen reports 570,000 unique domestic web visitors in Sept for Zagat; Yelp estimated at 9.4 million for same period
2011	Zagat acquired by Google	Acquired by Google for \$151 million in cash. Estimates suggest Zagat does \$30-\$40 mil/year in revenue
2013	Online coverage	Number of cities covered online dropped from 30 to 9
	Layoffs	Google does not renew contract of Zagat staff working as contract labor
2016	New app released	Ratings re-scaled to Yelp's five star format; app paired with Google's location-based services
2016	Coverage	Zagat guidebook coverage peaks at 2237 NYC restaurants
2018	Zagat sold by Google to The Infatuation	Sold by Google to the Infatuation (terms undisclosed, but presumed to be a fraction of Google acquisition costs). Zagat remains a separate line of business

Year	Commentor Type	Commentor	Topic	Quote	Source Citation	Archived Hyperlink
1987	Consumer and Survey Respondent; Investment Banker and former Deputy Mayer of New York	Carol Bellamy	Democratizing Ratings provide a Sense of the Landscape	"'It's just us average folks telling each other what we like."	Scardino, A. (1987) "New Yorkers & Co.; Reviews of 740 Restaurants With Not a Critic in Sight." New York Times. Dec. 28, Section D, Page 1.	https://web.archive.org/web /20150524213840/https://w ww.nytimes.com/1987/12/ 28/business/new-yorkers-co- reviews-of-740-restaurants- with-not-a-critic-in- sight.html
1989	Restaurant Owner of Chez Louis	David Liederman	Managers' Concern about Zagat Ratings Legitimacy	"I am convinced that people play games with those forms. It is possible for someone to review restaurants he or she has never been to. It can be statistically deranged."	Hall, T. (1989) "Zagat Restaurant Guides: Whose Voice is Being Heard?" New York Times. Feb. 8, Section C, Page 1.	https://web.archive.org/web /20171220002403/https://w ww.nytimes.com/1989/02/ 08/garden/zagat-restaurant- guides-whose-voice-is- being-heard.html
1989	Restaurant Owner of Montrachet	Drew Nieporent	Managerial Beliefs that Consumer Ratings are Sticky	"If you had a bad experience three years ago, you're going to slam that restaurant"	Hall, T. (1989) "Zagat Restaurant Guides: Whose Voice is Being Heard?" New York Times. Feb. 8, Section C, Page 1.	https://web.archive.org/web /20171220002403/https://w ww.nytimes.com/1989/02/ 08/garden/zagat-restaurant- guides-whose-voice-is- being-heard.html
1989	Restaurant Owner of Primavera	Nocola Civetta	Managers Believe Zagat Ratings Drive Consumer Behavior	"'It brings a lot of people."	Hall, T. (1989) "Zagat Restaurant Guides: Whose Voice is Being Heard?" New York Times. Feb. 8, Section C, Page 1.	https://web.archive.org/web /20171220002403/https://w ww.nytimes.com/1989/02/ 08/garden/zagat-restaurant- guides-whose-voice-is- being-heard.html
1995	Restaurateur Planning to Start Restaurant	-	Owners Think they Need to be on Good Terms with Zagat	"I'm opening a restaurant soon, so I got to be nice to you [Tim Zagat]."	Weber, B. (1995) "With a gimlet eye on restaurants; Zagat (the man, not the book) makes his nightly rounds." New York Times. Apr. 9.	https://web.archive.org/web /20150526142649/https://w ww.nytimes.com/1995/04/ 09/nyregion/with-gimlet- eye-restaurants-zagat-man- not-book-makes-his-nightly- rounds.html
1997	Food Reporter Describing Managerial Responses to Ratings	Florence Fabricant	Managers Pay Attention to and Respond to Ratings- even if not Favorable or they Disagree	"Zagat has become a closely followed report card for chefs and restaurateurs, some of whom have complained over the years that the pithy comments that accompany the ratings (quotations from its citizen-reviewers) are too often selected to reflect the bias of the publishers rather than a consensus of the respondents."	Fabricant, F. (1997) "Zagat's New York Survey: Entries Up, Contributions Off." New York Times. Nov. 12, Section F, Page 4.	https://web.archive.org/web /20150527055557/https://w ww.nytimes.com/1997/11/ 12/dining/zagat-s-new-york- survey-entries-up- contributors-off.html
1998	Restaurateur, consultant and food writer.	George Lang	Restaurateurs believe that Ratings shape Consumer Behavior	"Well-informed professional critics are important to the elite restaurant-goer and to the industry, but the vox populi that Zagat reflects matters just as much to the great mass of American restaurant clients."	Apple Jr., R.W. (1998) "Zagat at 20: Populist, and Powerful." New York Times. Nov. 11, Section F, Page 1.	https://web.archive.org/web /20150527081510/https://w ww.nytimes.com/1998/11/ 11/dining/zagat-at-20- populist-and-powerful.html
1999	Consumer Letter to Editor about Ratings	Shaun Breidbart	Ratings are Sticky due to Selection Bias	"Such guides also suffer from repeat- customer bias. That is, people who ate at a restaurant once and hated it do not go back and thus don't review the restaurant ever again. But those who like the restaurant and frequent it, review it year after year."	Breidbart, S. (1999) "Flaws in Restaurant Guides." New York Times. Dec. 22, Section F, Page 12.	https://web.archive.org/web /20150527104428/https://w ww.nytimes.com/1999/12/ 22/dining/l-flaws-in- restaurant-guides- 015750.html

2000	Restaurant Consultant	Malcolm M. Knapp	Restaurateurs act upon their Belief that Ratings reflect Reality	The Zagat ratings are "a pretty good reflection of where things are."	Pristin, T. (2000) "Zagat Survey Reflects Restaurant Boom." New York Times. Oct. 23, Section B, Page 3.	https://web.archive.org/web /20150527140931/https://w ww.nytimes.com/2000/10/ 23/nyregion/zagat-survey- reflects-restaurant- boom.html
2007	Restaurant Owner of the Slanted Door in SF	Charles Phan	Managers must Respond to Technological Changes in Restaurant Industry	"All restaurants have to do it, whether you like it or not."	Hafner, K. (2007) "Restaurant Reservations Go Online." New York Times. Jun. 18.	https://web.archive.org/web /20120119144244//https://w ww.nytimes.com/2007/06/ 18/business/18opentable.ht ml
2008	Executive Vice President, Nielsen Online Strategic Services	Pete Blackshaw	Both Consumers and Firms are Seeing Opportunities with Online Ratings Information	"Consumers are rating and reviewing, ranting and raving, and the creative output is useful for other consumers. And it's giving companies really good data."	Fost, D. (2008) ""The Coffee was Lousy. The Wait was Long." New York Times. May 21.	https://web.archive.org/web /20180105073912/http://w ww.nytimes.com/2008/05/ 21/business/smallbusiness/ 21yelp.html
2008	Marketing Director for Kimpton (boutique hotels and restaurants)	Liz Johannesen	Managers Recognize the Importance of Digital Ratings	"It's [Yelp] an exciting new channel for us to harvest. We went from disbelief to suspicion to fully embracing it."	McNeil D.G. (2008) "Eat and Tell." New York Times. Nov. 4.	https://web.archive.org/web /20111030081425/https://w ww.nytimes.com/2008/11/ 05/dining/05yelp.html
2009	Law Partner, Duane Morris	Daniel Winslow	Online Ratings Help to Coordinate Client Events when Traveling	"I got hooked on Yelp as a way to find places on the road, and even in Boston, for clients. For example, I needed to find a vegan restaurant for a Hollywood actor who was in Boston shooting a TV pilot. Even though I live here, I'm not vegan and so I had no idea where to take him, but Yelp helped me find a great place. Part of the feel of any meeting is the feel of the restaurant, especially for a first meeting. So much of client development is the social aspect."	Kelly, C. (2009) "Facebook Status? In Town and Wondering What to Do." New York Times. May 6.	https://web.archive.org/web /20150906202726/https://w ww.nytimes.com/2009/05/ 07/business/businessspecial /07info.html
2009	Restaurateur	Dan Simons	Online Ratings have become Central to Business	"Social media for business now is life or death. You could open a business and do everything right, but if you're unaware of these social media you will perish. Social media can take a business and put a bullet in it."	Pattison, K. (2009) "Managing an Online Reputation." New York Times. July 29.	https://web.archive.org/web /20150330235045/https://w ww.nytimes.com/2009/07/ 30/business/smallbusiness/ 30reputation.html
2011	Online Ratings Manager; Google's vice president for local, maps, and location services	Marissa Mayer	Digital and Mobile Technologies have Accelerated Ratings Impact	"All of these are users wondering where they should go, where they should spend their time, so to be able to offer accurate information is important, and that's why we've been getting focused on reviews."		https://web.archive.org/web /20220701001738/https://ar chive.nytimes.com/dealboo k.nytimes.com/2011/09/08/ google-to-buy-zagat/
2012	Interim Restaurant Critic, New York Times	Eric Asimov	The Speed of Digital Ratings have Changed the Nature of Evaluations	"Social media and smartphones allow the real-time chronicling of any restaurant meal, by anybody, always. Web sites like Yelp permit instant critiques from anybody, including those with hidden agendas. The acceleration of judgments demands a faster response from professionals, who no longer can be so leisurely in their evaluations."	Asimov, E. (2012) "Eric Asimov: How the view from the critic's perch has changed." New York Times. Jan 3.	https://web.archive.org/web /20180224192048/https://w ww.nytimes.com/2012/01/ 04/dining/eric-asimov- reflects-on-his-brief-stint-as- interim-restaurant- critic.html
2012	Vice President for Consumer Products and Mobile at Yelp	Eric Singley	Enhanced Incentives for Managers to Game the Ratings System	"The bigger Yelp gets, the more incentive there is to game the system."	Streitfeld, D. (2012) "Buy Reviews on Yelp, Get Black Mark." New York Times. Oct. 18.	https://web.archive.org/web /20200613074134/https://w ww.nytimes.com/2012/10/ 18/technology/yelp-tries-to- halt-deceptive-reviews.html

Figure A6. Growth in Number of Restaurants Covered by Yelp, 2005-2015

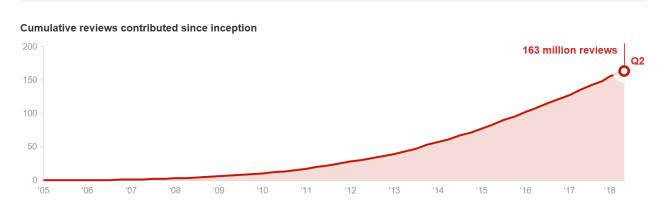

These figures compare the mean and median number of restaurants per ZIP code as recorded by Yelp and CBP between 2004 (when Yelp was founded) to 2015, in all ZIP codes covered by both sources. Yelp Opened shows the mean and median number of restaurants opened that year per ZIP code as recorded by Yelp. Yelp Closed represents the mean and median number of restaurants closed that year per ZIP code as recorded by Yelp.

Note. Figure source is Glaeser, Kim, and Luca (2017).

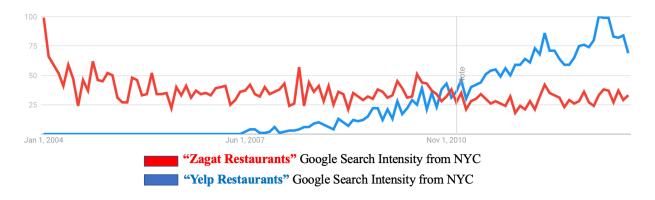

Figure A7. Growth in Number of Restaurant Reviews in Yelp, 2005 - 2018

Review Statistics as of June 30, 2018

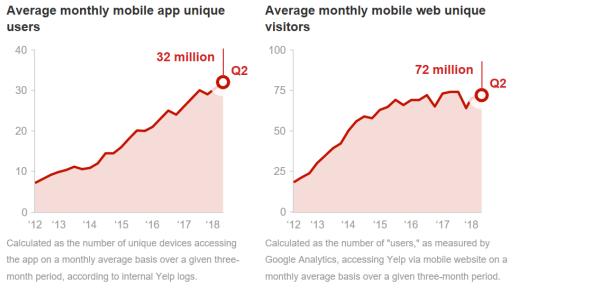

Note. Expansion in cumulative reviews on *Yelp* since its inception in 2005. Source is *Yelp Analytics*. Note that cumulative reviews have increased to more than 205 million by the end of 2019 per page 1 of Yelp's 10K filing on Dec. 31, 2019: https://www.sec.gov/Archives/edgar/data/1345016/000134501620000009/yelp-20191231.htm

Figure A8. Google Search Intensity for Zagat Restaurants and Yelp Restaurants, Originating in New York City 2004 - 2014

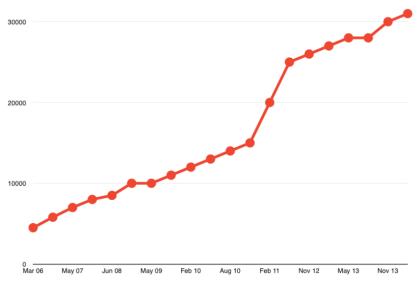

Note. Source material is from *Google Trends* data of searches originating in New York City.

Figure A9. Growth in Number of Average Unique Mobile/Web Users in Yelp, 2012 - 2018

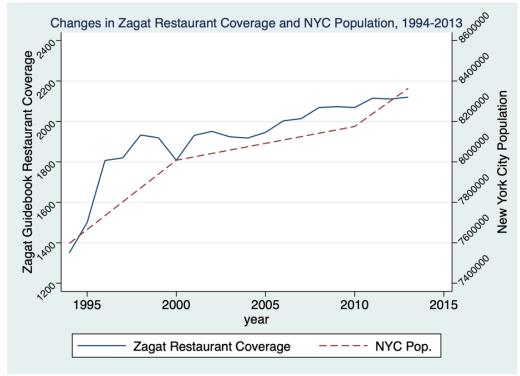

Note. Notable growth in mobile users and visitors to Yelp. Figure source is Yelp Analytics.

Figure A10. Growth in Number of Restaurants Using OpenTable, 2006 - 2013

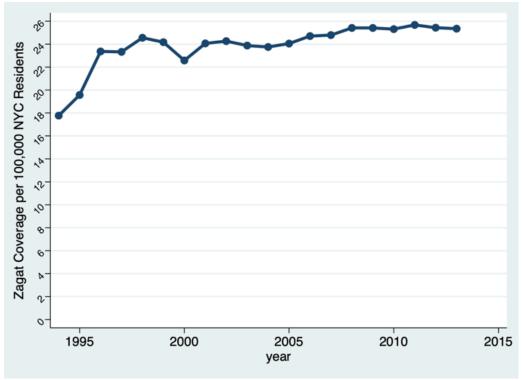

Note. Extensive growth in restaurants using *OpenTable*. Source material is *Eater* from 2014 and available at https://web.archive.org/web/20180331210736/https://www.eater.com/2014/6/13/6207641/opentable-by-the-numbers-from-launch-to-2-6-billion.

Figure A11. Zagat Restaurant Coverage and New York City Population by Year, 1994-2013

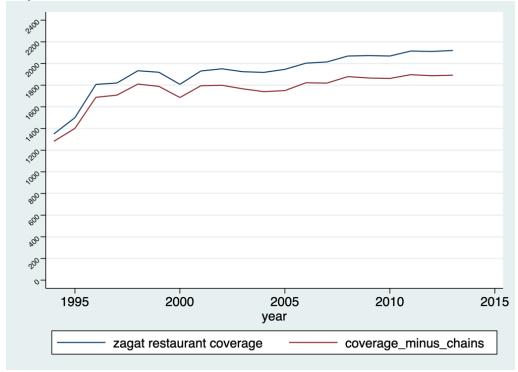

Note. Correspondence between Zagat restaurant coverage and New York City population growth. Population interpolations from 1990, 2000, 2010, 2020 US Decennial Censuses.

Figure A12. Zagat Restaurant Coverage per 100,000 New York City Residents by Year, 1994-2013

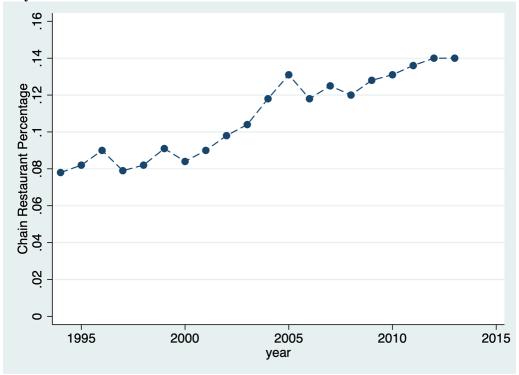

Note. Relative static changes in Zagat restaurant coverage per New York City population. Population interpolations from 1990, 2000, 2010, 2020 US Decennial Censuses.

Figure A13. Zagat Coverage for Chain and Non-Chain Restaurants by Year, New York City 1994-2013

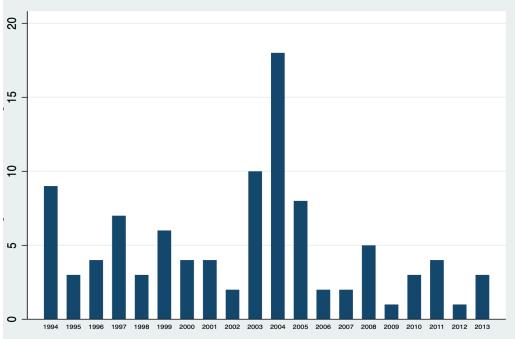

Note. Relative stability in Zagat coverage for all and non-chain restaurants.

Figure A14. Percent of Zagat Guidebook Entries as Chain Restaurants by Year, New York City 1994-2013

Note. Slight increase in chain restaurant coverage as a proportion of overall Zagat entries. Overall, chain restaurants expanded from 8% to 14%.

Figure A15. Zagat Entry and Text References to Restaurant Management, Ownership, or Name Changes, New York City 1994-2013

Note. Infrequent entry and text references to managerial, ownership, or name changes in restaurants.

Figure A16. Overall Zagat Ratings Distribution, New York City 1994-2013

Note. Restaurant ratings distribution around overall mean of 18.5.

10

5

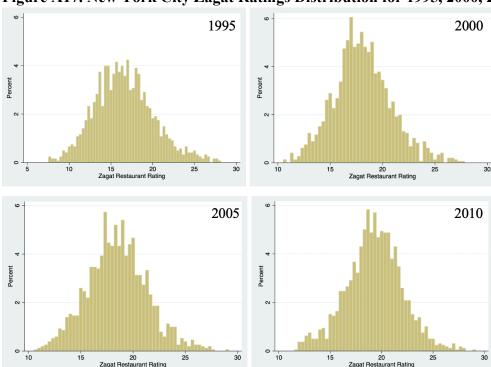

Figure A17. New York City Zagat Ratings Distribution for 1995, 2000, 2005, 2010

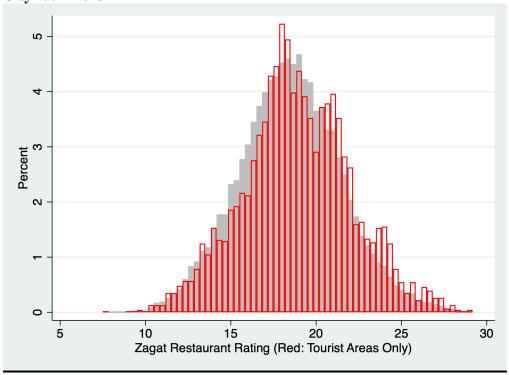

25

30

15 20 Zagat Restaurant Rating

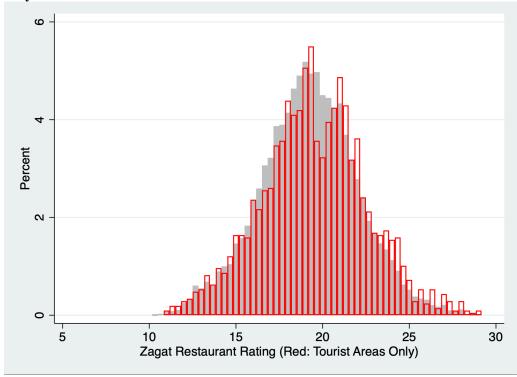

Note. Restaurant ratings distribution for selected year around overall means of 16.6 (1995), 18.1 (2000), 18.5 (2005), and 19.3 (2010).

Figure A18. Zagat Ratings Distributions of All and Tourist Area Restaurants, New York City 1994-2013

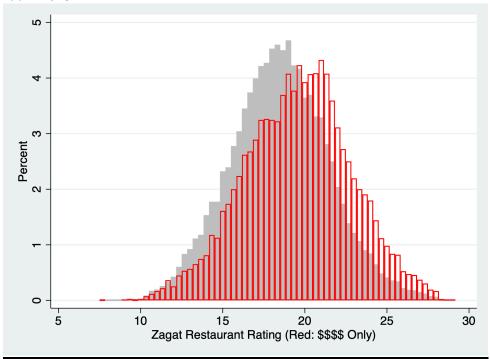

Note. Distributions of ratings for all restaurants compared to tourist area restaurants (overlayed in red). The mean rating for all restaurants is 18.47, while the mean for tourist area only restaurants is 18.91.

Figure A19. Zagat Ratings Distributions of All and Tourist Area Restaurants, New York City 2005-2013

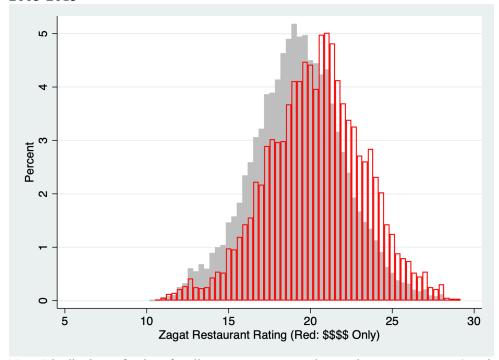

Note. Distributions of ratings for all restaurants compared to tourist area restaurants (overlayed in red) in the post-expansion era. The mean rating for all restaurants is 19.23 while the mean for tourist area only restaurants is 19.49. The relative distributions are like the pre-expansion era (see Figure A18).

Figure A20. Zagat Ratings Distributions of All and Expensive Restaurants, New York City 1994-2013

Note. Distributions of ratings for all restaurants compared to tourist area restaurants (overlayed in red). The mean ratings for all restaurants is 18.47, while the mean for expensive restaurants is 19.58.

Figure A21. Zagat Ratings Distributions of All and Expensive Restaurants, New York City 2005-2013

Note. Distributions of ratings for all restaurants compared to tourist area restaurants (overlayed in red) in the post-expansion era. The mean ratings for all restaurants is 19.23 while the mean for expensive restaurants is 20.34. The relative distributions are similar to the pre-expansion era (see Figure A20).

Zagat Rating City

Figure A22. Mean Zagat Rating by Year, New York City 1994-2013

Note. Mean ratings show a steady but moderate overall increase from 16.9/30 in 1994 to 20.7/30 in 2013. There is also a notable reduction in restaurants receiving a mean rating of less than 15. 21% of restaurants had a score of less than 15 between 1994-1999, 11% between 2000-2004, 8% between 2005-2009, and 4% between 2010 and 2013.

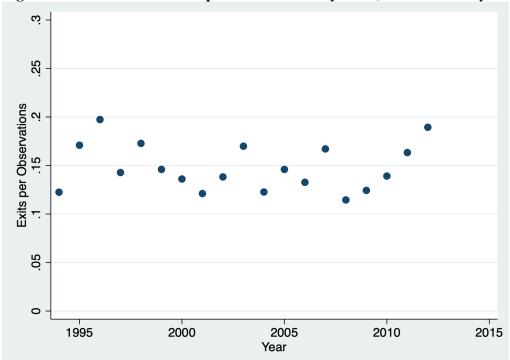

Figure A23. Restaurant Exits per Observation by Year, New York City 1994-2013

Note. Steady proportion of restaurants exits by year. Mean 14.8% per year; min. 11.5% (2008); max. 19.7% (1996).

Mean Rating for Exiting Restaurants by Tear, New Tork City

Mean Batting for Exiting Restaurants by Tear, New Tork City

8 4 0 15 14 16 18 20 25 24 26 28 30

8 4 0 15 14 16 18 20 25 24 26 28 30

Figure A24. Mean Rating for Exiting Restaurants by Year, New York City 1994-2013

Note. Consistent ratings for exiting restaurants over time; exit year mean rating 17.3.

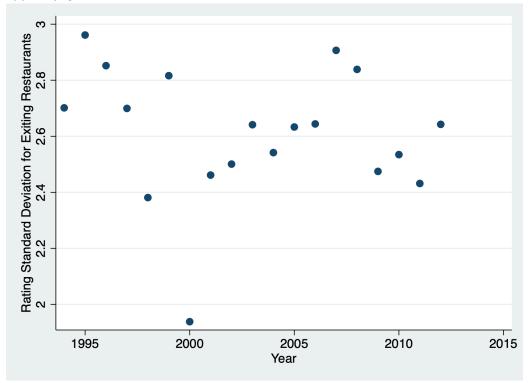

Year

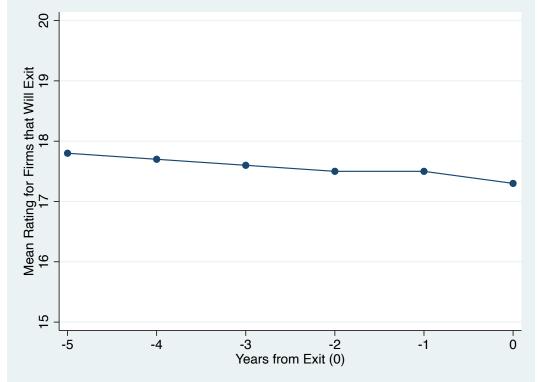

Note. Exiting restaurants consistently show ratings below the yearly mean, with no clear time-trend; mean score for exiting restaurants is -1.03 points below year mean on average.

Figure A26. Rating Standard Deviation for Exiting Restaurants by Year, New York City 1994-2013

Note. Distribution of standard deviation in ratings for exiting restaurants.

Figure A27. Ratings Trajectory for Exiting Restaurants, New York City 1994-2013

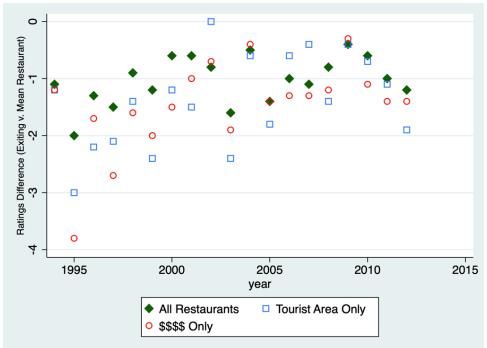

Note. Ratings for exiting restaurants are relatively static over time, indicating that significant changes in within-firm ratings are likely not driving exits.

Figure A28. Tourist Area and Expensive Restaurant Exits per Observation by Year, New York City 1994-2013

Note. Steady proportion of restaurant exits by year observations for all, tourist, and expensive restaurants. Mean exit percentages: 14.8% for all restaurants; 11.7% for tourist area restaurants; and 13.5% for expensive restaurants.

Figure A29. Ratings Underperformance of Exiting Restaurants by Year, New York City 1994-2013

Note. Y-axis represents the ratings differential between exiting restaurants and the mean of all restaurants. \$\$\$\$ tier, and tourist area only restrict observations by price tier and geography, respectively. This figure underscores that exiting restaurants consistently underperform the mean restaurant throughout the entire period of investigation. The overall mean underperformance for all restaurants is -1.03 (-5.7%), expensive restaurants only is -1.47 (-7.7%), and tourist area restaurants only -1.38 (-7.4%). These means are not statistically different from each other at conventional levels.

Exhibit A6. Nina Zagat Interview Statement on Restaurant Comparability

Nina Zagat provided an example of the challenge in establishing comparability across restaurants in a 2007 interview. We note that this underscores that the competitor definition challenge described in the paper has both *within* and *between* person dimensions. Moreover, this multidimensionality of competition is likely further complicated when trying to optimize preferences subject to various constraints across several individuals:

Each one of us, we think, is a different person on it [Zagat] each night. The night you're tired and you're going home from work after writing a story and you just want something simple to eat before you go to bed and it's not too expensive, you're not looking for a three-star or two-star experience. Basically, you're looking for something near your office or near your home or in between.

Tomorrow night, you're meeting a friend who is out of a job and you know that that person is going to have to share the cost, so you're doing a different kind of restaurant that is light, casual. Another night you're going to the movies and you want something near the movies that is quick, say, a hamburger, a salad, something of that kind. Another night you are taking your children who are five and six years old out, and they have to be able to get up and run around the table and spill and probably the worse the place looks the better because the five and six year olds have to be the ones you're thinking about. Another night, you're taking a client out and it depends on where the client is staying, depends on what the client – how sophisticated the client is. If it's a very sophisticated person who's been to New York before, you may want to take them to Per Se or something that it is – you're going to be trying to show them something they haven't seen before that is wonderful and unusual. On the other hand, if it's a client who's never been to New York before, you may want to take them to the Rainbow Room or Tayern on the Green.
