## Appendix S1

## A Procedure

Here we describe the total inference procure following alignment of the type A and B reports and the ActivPAL data. Such a procedure is repeated for every participant.

## Step one (association within the wider tracking area)

- Search through the aligned type B report data for times when reports are absent for a time greater than a minimum cutoff of 10 seconds
- Associate such times as being outside of the wider tracking area.

## Step two (association during stationary periods)

- Within times where the participant has not been determined to be outside of the wider tracking area search through the aligned activPAL data for periods of time that are comprised entirely of standing or sitting and are at least 30 seconds long
- For each time period perform an average of the $x$ and $y$ positions of the stationary tags associated with each report in the time period. For instance if there are two reports from tag 1 with position $(10,20)$ and one report from tag 2 with position $(15,25)$ the average $x$ position is $\bar{x}=(10+10+15) / 3$ and the average $y$ position $\bar{y}=(20+20+25) / 3$.
- Find the stationary tag closest to $(\bar{x}, \bar{y})$ and then the immediate tracking area within which that tag is located.
- Determine the location of the participant for every second within such a stationary period to be that immediate tracking area.
- If no type A reports are within the period associate the participant with connecting space.
This procedure results in periods of time where the participant's location has been determined and interleaving periods where the participant is found within the wider tracking area, but their location has yet to be determined. In those interleaving periods the third step is followed.

## Step three (association during remaining periods)

- For each second in the remaining interleaving time periods perform an average of the $x$ and $y$ positions of the stationary tags associated with
type A reports that occur within two seconds forwards and backwards in time from the time being considered (five seconds total). Again if there are two reports from tag 1 with position $(10,20)$ and one report from tag 2 with position $(15,25)$ the average $x$ position is $\bar{x}=(10+10+15) / 3$ and the average $y$ position $\bar{y}=(20+20+25) / 3$.
- Find the stationary tag closest to $(\bar{x}, \bar{y})$ and then the immediate tracking area within which that tag is located.
- Determine the location of the participant for the second being considered to be that immediate tracking area.
- If no type A reports are found, but no steps have been performed since the participant's last successful association with an immediate tracking area, associate the second with the last known immediate tracking area.
- If no type A reports are found and steps have been performed since the last known immediate tracking area, associate the time with connecting space.

## Step four (noise reduction)

- Search through the entire data structure of ActivPAL codes and determined location.
- If the participant is associated with a location for less than five seconds replace the associated location of such times with connecting space.
- If the participant is associated with an unbroken sequence of different immediate tracking areas (i.e. with no time associated with connecting space) then the stationary tag positions within those immediate tracking areas are considered. If it is possible to choose a stationary tag from each immediate tracking area in the sequence such that all are within 2 m of each other and fewer than five steps have been taken during that time the sequence is simplified. When this occurs the participant is associated with the most common immediate tracking area in the sequence for the duration of the sequence.

## B Detailed Results

## B. 1 Data inclusion rules

To reach the final working data set two separate data streams had to be combined. However, each are separately vulnerable to missing data such that there are periods of time where one or more is missing or unreliable which can arise from failures to follow wearing protocol for either the tracking tag or the ActivPAL device or administering/collection of one device before the other. As such, to obtain the final data stream upon which we could perform our inference procedure, we procedurally ran through the combined data and removed sections where one or more types of data were missing or unreliable and did so in a specific sequence. First we established the total amount of time when there was tracking system data, identifiable by the first and last instances of presence
of the participant tag within the wider tracking area. We then removed periods of time where ActivPAL data was missing, typically arising from a subsequent administering of the device after the tracking tag. Next we removed periods of time for which the ActivPAL data was deemed to be untrustworthy usually from poor adherence to protocol such as taking the device off confirmed by participant feedback. Next we removed periods of time for which the tracking system data indicated poor adherence to protocol resulting in poor resultant data. For instance when a tag is found exclusively in one location despite plausible and significant activity according to the ActivPAL device it is possible the participant tag has been taken off. The inference procedure was performed on the remaining time consisting of reliable and coincident ActivPAL data and type A and type B transmission reports. From the resultant location data that resulted from the inference procedure, the proportion of the time within the wider tracking area for which the participant had been associated with an immediate tracking area was calculated. If this value was less than $80 \%$ the participant was excluded from the data set on the grounds of insufficient data quality. Each of these steps is illustrated for all participants in the two deployments included in this study in Table A. Also included are the effects such data exclusion had on direct observations for each participant.

Table A: Summary of excluded data and the effect on utilised direct observations

## B. 2 Complete participant results

Tables B \& C show, for all participants across both deployments, the measured movement variables such as time spent sitting/standing, the number of sitting to standing to transitions and number of steps per unit time. Also included are the number of trips to kitchens and bathrooms in absolute and per hour terms alongside sample wide mean and standard deviation figures where appropriate.

Table C: Trip data using valid data for included participants

## C Additional figures

Figure A: Trip timing within the working day. Distribution of the time at which trips to kitchens and WCs occur for all participants within each building case study ( $\mathrm{n}=33$ ).

Figure B: Time spent at trip locations. Distribution of time spent in WCs and kitchens derived from all participant data across both case study buildings ( $\mathrm{n}=33$ ).

Figure C: Waiting time between trips. Distribution of time between trips to WCs and kitchens and between specific trip numbers derived from all participant data ( $\mathrm{n}=33$ ).
