Highlights.

- Ketogenic diet treatment in infants with refractory epilepsy is effective and can be done safely.
- Ketogenic diet must be adjusted to specific nutritional requirements of infants.
- Monitoring during initiation and follow up is required by a multidisciplinary team.

Keywords.

Infant, Ketogenic diet, refractory epilepsy, guidelines

Abstract

The ketogenic diet (KD) is an established, effective non-pharmacologic treatment for drug resistant childhood epilepsy. For a long time, the KD was not recommended for use in infancy (under the age of 2 years) because this is such a crucial period in development and the perceived high risk of nutritional inadequacies. Indeed, infants are a vulnerable population with specific nutritional requirements. But current research shows that the KD is highly effective and well tolerated in infants with epilepsy. Seizure freedom is often achieved and maintained in this specific patient group.

There is a need for standardised protocols and management recommendations for clinical use. It is desirable that consensus is reached with regard to guidance on how the diet should be administered and in whom. In April 2015, a project group of 5 experts was established in order to create a consensus statement regarding the clinical management of the KD in infants. The manuscript was reviewed and amended by a larger group of 10 international experts in the KD field.

The resulting recommendations include patient selection, pre-KD counseling and evaluation, specific nutritional requirements, preferred initiation, monitoring of adverse effects at initiation and follow-up, evaluation and KD discontinuation. This paper highlights recommendations based on best evidence, combined with expert opinions and gives directions for future research.

1. Introduction/background

The ketogenic diet (KD) is a non-pharmacologic treatment for children with drug resistant epilepsy. The efficacy of the KD has been established by several multicenter studies and one randomized controlled trial. The randomized trial that further established the efficacy of KD was conducted in children and adolescents aged 2 to 16 years [1]. The diet may be administered in one of several ways and each may be valid. An international protocol for its implementation and subsequent follow-up management in children has been published [2] and recently updated (ILAE 2015) [3] .

For a long time, the KD was not recommended for use in infancy (under the age of 2 years) in view of it being such a crucial period of development and the perceived high risk of nutritional inadequacies. This was based on the knowledge of immaturity of lipase activity, liver function and lipid metabolism and the difficulty of achieving and maintaining ketosis.

The first reports by Nordli et al in a small group of infants showed the KD to be effective and safe [4]. A KD formula with ratio 3:1 is now available making the diet easier to administer in this group as first or second line treatment. The most recent study by Dressler et al showed the KD to be highly effective and well tolerated in infants with epilepsy. Seizure freedom appears to be often achieved and maintained in this age group[5].

Because international KD guidelines do not contain specific advice for infants, recommendations for optimal practice in this group are needed. Infants are a vulnerable population with specific nutritional requirements. It is therefore desirable that consensus is reached with regard to guidance on how the diet should be administered and in whom.

2. Methods.

At the Dietary Management of Inherited Metabolic Diseases (DMIMD) conference 2015 in London an initial meeting was held with the goal of starting a working group of experts in KD treatment in infancy. A group of five experts (i.e two pediatric neurologist and three dietitians, see appendix I) discussed issues with regard to specific recommendations for this group of patients and designed the framework based on subjects they found applicable. During teleconference calls several subjects were addressed. A larger group of international experts (i.e. 3 pediatric neurologists and 7 dietitians, see appendix I) on KD treatment in infants were asked to send their guidelines or, in absence of recent published literature on subjects, information based on their professional or center's experience. These experts also reviewed the full manuscript of the recommendations. After two rounds of review, consensus was reached on the final text.

The questions to be answered were:

- Which epilepsy syndromes in infancy benefit most from KD treatment?
- How should KD initiation be considered in infants?
- Which version of KD is feasible and safe in infancy and how should the KD be initiated?
- What are the dietary prescriptions for infants in respect to their specific nutritional requirements?
- How should the KD be monitored during treatment at baseline and follow up and which are the most important adverse effects to be expected?
- How should the diet be implemented in emergency situations?
- After what period of time should efficacy of KD treatment be evaluated and/or the diet discontinued?
- What are the future directions for research?

3. Epilepsy syndromes in infancy where KD is of benefit.

Management of epilepsy in infancy is challenging based on the characteristics of the epilepsy and its impact on neurodevelopment of the child. This implies early, aggressive and optimal treatment is warranted. As a non-pharmacological treatment KD is currently used in infants with refractory epilepsy syndromes (see table 1) such as infantile spasms (West syndrome) resistant to first line medication [6-10], Ohtahara syndrome [11, 12], epilepsy of infancy with migrating seizures [13] and resistant epilepsy with focal seizures awaiting epilepsy surgery. There are also other conditions for which the KD is the treatment of choice such as glucose transporter type 1 (GLUT-1) deficiency [14] and pyruvate dehydrogenase complex (PDHC) deficiency [15] .

Table 1. Indications and contra indications of KD in infants.

Indications	Contra-indications
<p><i>Epilepsy:</i></p> <ul style="list-style-type: none"> - Refractory epilepsy after use of 2 anti-epileptic drugs (AEDs): i.e. <ul style="list-style-type: none"> - West syndrome - Ohtahara syndrome - with focal seizure waiting for epilepsy surgery <p><i>Metabolic diseases:</i></p> <ul style="list-style-type: none"> - GLUT-1 deficiency - PDHC deficiency optional: <ul style="list-style-type: none"> - Mitochondrial diseases 	<p><i>Absolute:</i></p> <ul style="list-style-type: none"> - Fatty acid oxidation deficiencies (VLCAD, LCHAD, MCAD, OCTN2, CPT1, CPT2) - Pyruvate carboxylase deficiency and other gluconeogenesis defects (fructose 1,6 diphosphatase deficiency) - Glycogen storage diseases (except type 2) - Ketolysis defects - Ketogenesis defects - Porphyria - Prolonged QT syndrome or other cardiac diseases - Liver, kidney or pancreatic insufficiency - Hyperinsulinism <p><i>Relative</i></p> <ul style="list-style-type: none"> - Inability to maintain adequate nutrition - Surgical focus identified by neuroimaging and video EEG monitoring - Parent or caregiver non compliance - Growth retardation - Severe gastrointestinal reflux - Familial hypercholesterolemia

4. Preparing for treatment.

Treatment with the KD is demanding for families and requires a high degree of medical and dietetic monitoring because of possible side effects and restrictiveness. A multidisciplinary team is highly recommended (pediatric neurologist/pediatrician, epilepsy nurse, dietitian and close cooperation with pharmacy).

At baseline detailed information is obtained on the medical, nutritional and biochemical status of the infant. After a positive decision an individualized KD and step by step plan will be designed.

5. Dietary prescription.

5.1 Which diet to choose and how to initiate.

KD is a high fat (71-90 % energy) and carbohydrate restricted (5-19 % energy) diet that contains adequate amount of protein to support growth. Clinical practice shows the classical version of the KD with a 3:1 ratio is routinely used in infants in order to meet protein requirements. This means that for every 3 grams of fat there is 1 gram of combined protein and carbohydrate. Several studies show the range of KD ratio used is 2.5-4:1 with respect of tolerance, ketosis and side effects [6-8, 10].

Information in the literature on how the KD should be initiated in infants is scarce. Raju et al (2011) showed in a randomized trial of 38 infants that a 2.5:1 ratio KD was as effective as 4:1 ratio KD but less side effects were seen [16]. Pires et al (2013) showed in a prospective trial of 17 infants receiving a KD during hospitalisation that a 3:1 (some 4:1) ratio was very effective and tolerated well. Diet initiation was performed by a non-fasting protocol with daily steps of increasing calories and ratio [7].

Information from expert teams show infants are admitted to hospital for diet initiation performed without fasting and by an individualized step by step plan. Most centers start with a 1.0:1 ratio with full calories, increasing the ratio on a daily basis to 3:1 based on tolerance.

Recommendations: all young infants (< 12 months) should be admitted to hospital. Diet initiation should be undertaken without fasting and a stepwise start commencing with a 1:1 ratio. A build to a classical KD with 3:1 ratio is recommended. The diet can be adjusted to a lower ratio (2.5 or 2:1) or higher ratio (3.5 or 4:1) based on level of ketosis and tolerance. A KD formula with ratio 3:1 can be used purely or combined with breast milk. Careful calculation to check individual requirements are met is highly recommended especially when a 4:1 ratio is applied.

5.2 Energy.

The energy requirements of infants with epilepsy may vary greatly. There is no consensus in the literature on how to calculate energy requirements in infants below 6 months of age.

Often a percentage (75% - 100%) of the recommended daily allowance (RDA) of energy is used; sometimes an individual calculation is reported based on dietary history [2, 4, 17].

For infants with severe disability such as encephalopathy with epilepsy and severe motor involvement, a calculation of the expected energy requirement based only on the Schofield formula is not very accurate below 10 kg and/or age 12 months.

The total energy requirement depends on the physical activity that may be influenced by epileptic seizures, the anti-epileptic drug (AED) used and possibly the degree of spasticity or frequency of muscle spasm during epileptic seizures [18]. The RDAs are recommendations for groups of healthy children, making them less suitable for the individual with epilepsy but still the only validated recommendations available.

Recommendations: for infants the energy requirements have to be based on the intake recorded in the food diary, compared with the RDA for age and gender and recent growth.

If there is a recent decline in the growth curve or failure to thrive an additional amount of energy is necessary. Using the ideal weight/age or weight/height should be considered to ensure catch up growth. If infants have gained a large amount of weight (e.g. after adrenocorticotrophic hormone (ACTH) use), it is important to determine the most appropriate weight/age or weight/ height to be used for an adequate diet calculation. In individual cases resting energy expenditure (REE) can be measured with a ventilated hood on which factors for (catch up) growth and physical activity level (PAL) will be multiplied. The energy intake has to be adjusted frequently (sometimes on weekly basis) based on evaluation of growth curve, changes in level of activity and/or illness.

Table 2. Energy requirements for an infant on the KD based on RDA*.

Age/months	Weight/kg	Kcal/kg/day
1-3	3.8- 5.9	100-95
4-6	6.0 -7.9	95-85
7-12	8.0- 10.0	85-80

* RDA from Austria, France, Germany, The Netherlands, UK, USA.

5.3 Fat.

The classical KD is based on long chain triglyceride (LCT) and works with different ratios. Most infants use the classical KD at a ratio of 3:1. Based on individual tolerance and/or level of ketosis, a different ratio may be used (2:1 – 4:1).

Use of medium chain triglyceride (MCT) in infants will be limited. In older infants use of MCT 50% emulsion mixed with a (low fat) milk product (50-50) or a little amount of MCT

20% emulsion drink will be possible. The amount of MCT is tailored based on level of ketosis and tolerance.

The amount of total MCT well tolerated by the infant will be around 10-25% of daily energy intake.

5.4 Protein.

The protein requirements of infants with epilepsy are the same as in healthy infants. There is no consensus in the literature (primarily the classical KD) with respect to protein intake.

Often, 10 % energy combined protein and carbohydrate is assumed in which 1 gram of protein per kg body weight is recommended; sometimes a protein intake of 5-7 % energy is reported or reference is made to the RDAs.

With the classical KD, achieving an adequate protein intake in the ratio is at the expense of the allowed quantity of carbohydrate. Therefore for the young child with psychomotor delay, with a realistic chance of growth retardation, a ratio of 3:1 is usually chosen [4, 19].

Recommendations: for infants the protein intakes based on RDA are advised (see table 3).

If there is a recent decline in the growth curve or failure to thrive an adequate intake of protein is important. Using the ideal weight/age or weight/height should be considered to ensure catch up growth.

If infants have gained a large amount of weight it is important to determine the most appropriate weight/age or weight/height to be used for adequate diet calculation.

Aim for the optimal amount of protein and check that the amount of protein is above the minimal World Health Organisation (WHO) recommendation [20, 21]

The diet must be adjusted frequently (sometimes on weekly basis) based on weight gain.

**Table 3. Recommended daily protein intake for an infant on the KD
based on RDA or WHO/FAO.**

Age/months	Weight/kg (use ideal weight/age)	Protein g/kg/day during KD*	Protein/g/kg/day WHO/FAO
1-3	3.8- 5.9	2.0-1.6	1.77-1.36**
4-6	6.0 -7.9	1.5-1.3	1.24-1.12**
7-12	8.0- 10.0	1.2-1.1	1.12-0.86***

* Based on average RDA from Austria, France, Germany, The Netherlands, UK, USA.

** WHO 2007: safe level for growth +1.96 SD

*** FAO 2013

5.5 Carbohydrate.

The permitted quantity of carbohydrate follows from the calculation of energy and protein requirements and the establishment of the necessary quantity of fat.

The allowed quantity of carbohydrate is divided throughout the day to prevent adverse effects such as hypoglycaemia or excessive ketosis. Artificial sweeteners should be avoided in infants.

Introduction of solid foods, when age and developmentally appropriate, will increase the amount of fibre since constipation is a frequent adverse effect of the KD. The potential presence of resorbable carbohydrate in medication and supplements should not be overlooked.

Recommendations: the treating physician consults the pharmacist for suitable (alternative) sugar free medication.

5.6 Fluid.

In the past, the KD has been combined with a fluid restriction. It was believed that mild dehydration improved the efficacy of the KD. Theories that a fluid restriction influenced the pH, electrolytes or ketone concentrations of the blood and brain have been abandoned after various studies. According to Homer et al, no mechanism has been found that shows that over hydration has a negative effect on epileptic seizures [22].

Recommendations: fluid restriction might add to the development of kidney stones so an adequate hydration is required. An age and weight appropriate fluid intake is advised based on RDA, with fluid offered throughout the day. The fluid intake should be individually calculated and adjusted frequently based on weight gain and biochemistry results (e.g. urine calcium: creatinine ratio).

Table 4. Recommended daily fluid intake based on RDA*.

Age/months	Weight/kg	ml/kg/day
1-3	3.8- 5.9	150-140
4-6	6.0 -7.9	120-110
7-12	8.0- 10.0	100- 90

* Based on average of RDA from Austria, France, Germany, The Netherlands, UK, USA.

5.7 Vitamins and minerals.

The classical KD contains insufficient micronutrients [23, 24] The potential presence of absorbable / resorbable carbohydrate in vitamin/mineral supplements however should not be overlooked. It is known that various anticonvulsants have interactions with some minerals and vitamins, for example, influencing the absorption of folic acid and the metabolism of calcium and vitamin D [22].

Recommendations: by means of adequate supplementation, the intake of micronutrients should be individually calculated corresponding to reference intakes for age and weight. When starting to wean off a formula diet, micronutrient intake should be assessed and supplementation commenced as necessary (for example when formula intake contributes to less than 80% of energy requirements).

6. Treatment phase.

6.1 Baseline monitoring

Prior to the start of KD, laboratory and urine checks are strongly advised to ensure there are no pre-existing contra-indications or deficiencies (table 5) .

Table 5. Advised baseline monitoring [2]

<u>Investigation</u> <u>(baseline)</u>	
<i><u>Essential :</u></i>	<i><u>Recommended</u></i>
<u>Blood:</u> Full blood count	<u>Blood:</u> Vitamins A, E, B12
Renal profile (includes sodium, potassium, urea, creatinine, bicarbonate and albumin)	Zinc, selenium, copper
Liver profile	Folate, ferritin
Calcium, phosphate, magnesium	
Glucose	
Vitamin D	
Lipid profile (repeat with fasting if elevated)	
Free and acylcarnitine profile	
<u>Urine:</u> calcium:creatinine ratio haematuria , organic acids	

6.2. Monitoring during diet initiation.

6.2.1 General.

During diet initiation weight, nutritional intake, tolerance (i.e gastro intestinal disturbances, vomiting, etc.) are checked on a daily basis. Height and head circumference are measured at baseline.

While on a KD the infant can continue bottle feeding. In daily practice the majority of infants with severe epilepsy have feeding difficulties and may need an enteral tube feed at diet initiation to achieve their requirements.

It is possible to continue using a limited amount of expressed breastmilk combined/mixed with ketogenic 3:1 formula. If there is no expressed breastmilk a limited amount of standard infant formula can be used to combine/mix with the ketogenic formula.

This may be given by bottle and/or tube.

In some cases (i.e. the young infant) breastfeeding may be possible after a controlled amount of ketogenic formula is given, which highly depends on seizure reduction and on level of ketosis. In this situation the use of ketogenic 3:1 formula is recommended. In some of these cases ketogenic 4:1 formula may be necessary, but use this only after careful calculation and monitoring. In some cases (i.e. the young infant) breastfeeding on demand may be possible but this highly depends on seizure frequency and on level of ketosis.

6.2.2 Glucose.

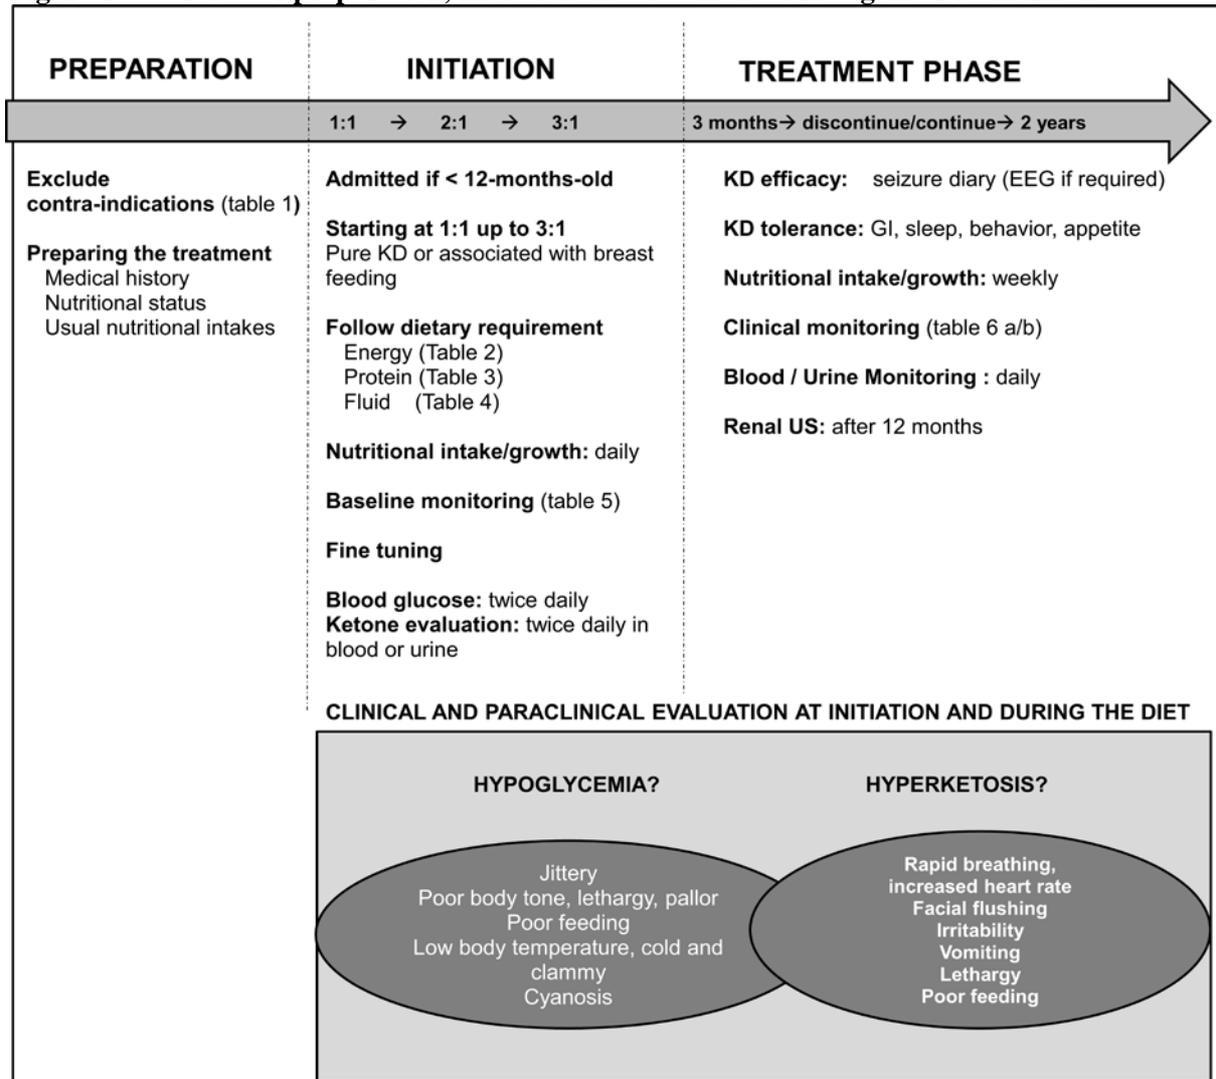

There is a risk of hypoglycaemia during diet initiation although uncommon in the absence of a metabolic disease. During initiation blood glucose should be checked twice daily (or more based on symptoms of hypoglycemia) and frequency must be adjusted based on tolerance.

Hypoglycemia is defined as glucose levels below of 2-2.5 mmol/l (approximately 40mg/dl) and should be treated immediately with 2-4 grams of carbohydrates. Infants with blood glucose > 3mmol/l but showing symptoms of hypoglycaemia (see figure 1) should also be treated in the same way. Blood glucose should be re-checked after 15-20 minutes and if not improved treatment should be repeated.

6.2.3 Ketones.

During transition to a ketogenic feeding regime or ketogenic food, the level of ketone bodies in the blood will increase. Monitoring of ketones will ensure a therapeutic level is reached without risking symptoms of excess ketosis (see figure 1). Ketones can be measured in blood or urine. Blood testing using a ketometer is recommended during diet initiation as this is more accurate and unaffected by urine dilution or any possible alterations in water homeostasis that may occur in very young infants. Blood ketones should be checked twice daily using a finger or heel prick. Hyperketosis is defined as 5 mmol/l or higher in blood and should be treated with 2-4 grams of carbohydrates. Blood ketones should be re-checked after 15-20 minutes and if not improved treatment should be repeated.

Figure 1: Overview of preparation, initiation and treatment of Ketogenic Diet in Infants

EEG: electroencephalogram, GI: GastroIntestinal.

6.2.4 Gastro-intestinal complaints.

Gastro-intestinal problems such as vomiting, nausea, diarrhea, and abdominal discomfort are common side effects of the KD [16, 25], however they can usually be alleviated with dietary manipulation and by altering the step by step initiation plan.

There is a risk that children with pre-existing gastro oesophageal reflux will have symptoms exacerbated by a high fat regime in view of delayed gastric emptying. Optimising anti-reflux medication will help alleviate the symptoms.

Constipation is the most common reported complication of the KD and may already be present prior to diet initiation. Despite dietary changes to help lessen the problem many children need additional treatment with medication.

When the amount of fat is increased gradually the risk of adverse effects will be limited.

6.3 Monitoring and adverse effects during follow up.

6.3.1 Glucose/ketones.

There is a risk of hypoglycaemia, acidosis, dehydration and high levels of ketones on commencing a KD [25] with increased risk of excess ketosis and metabolic acidosis with concurrent use of carbonic anhydrase inhibitors (for example, topiramate or zonisamide) [26].

6.3.2 Gastro intestinal complaints.

Gastro-intestinal problems such as vomiting, nausea, diarrhea and abdominal discomfort are common on-going side effects of the KD however can usually be alleviated with dietary manipulation, see section 6.2.4. [27, 28].

6.3.3 Growth.

There is evidence of impaired growth in children on the KD [29, 30]; younger children may be more at risk [19]. Long-term follow up of children treated with the KD in the past suggests that although growth does improve after the diet is discontinued, height gain can still be below expected [31]. Although growth retardation appears to be a problem in children on both classical and MCT KDs despite the latter providing a significantly higher protein intake [32], a prescribed protein-to-energy ratio of at least 1.5 g protein/100kcal has been suggested to help prevent growth faltering [33].

6.3.4 Nutritional deficiencies.

Children with drug resistant epilepsy are at risk of insufficient vitamin D status prior to starting a KD [34] and although levels can be normalised on diet therapy with vitamin D supplementation, a decline in both whole body and spine bone mineral content while on the KD has been reported [35] despite reduction in anticonvulsant medication.

Selenium deficiency has been reported in children on the KD [36] with the risk of impaired myocardial function [37].

Hypomagnesaemia has also been seen [25], and may be a particular problem in children on the classical KD despite micronutrient supplementation [23].

Vitamin C deficiency has been reported in one child on the KD [38] but plasma levels of fat soluble vitamins A and E can often be raised as a consequence of a high fat intake [23]. A fall in carnitine status of children and young adults during the first few months of the KD has been seen with some cases requiring supplementation [39], although levels tended to normalise with time on diet therapy.

6.3.5 Cardiovascular.

Plasma lipid levels can often be elevated by the KD and significant increases in atherogenic apoB-containing lipoproteins have been reported in children after 6 months of KD [40].

Although there is evidence of a trend back towards normal with time on the KD [41], this raises concern about long term adverse effects on vascular function. Studies suggest that while arterial stiffness may increase initially [42], the changes in arterial function observed within the first year of KD treatment are not significant after 24 months and appear to be reversible [43]. Further studies are required to investigate this issue.

6.3.6. Kidney stones.

The use of KD in infants might increase the risk of kidney stones compared to older children. In addition to the age factor, the presence of hypercalciuria also increases the risk for the development of kidney stones [44]. Uric acid, calcium oxalate, calcium phosphate or mixed composition stones have been reported in up to 7% of children on the KD [44-46]. Risk may be higher with long-term treatment [29] and concurrent use of carbonic anhydrase inhibitors [47]. The daily oral intake of citrate potassium that theoretically alkalizes the urine and solubilizes urine calcium can be suggested to prevent kidney stones, in particular in the patients with cumulating risk factors. A retrospective study comparing patients treated by KD with or without daily potassium citrate supplement has suggested a preventive effect [48].

6.3.7 Other side effects.

Other reported, but rare, side effects of the KD are increased infection risk, bruising, raised serum uric acid, fractures, pancreatitis, lipid-aspiration pneumonia, and cardiac abnormalities [25, 37, 49-51].

6.3.8 Adverse effects of the ketogenic diet reported in infants

Most commonly seen in infants were gastro-intestinal disturbances especially constipation and reflux, altered lipid levels, renal stones and acidosis. Most side effects were transient and could be controlled without diet withdrawal by a high level of monitoring as recommended in table 6 A and B. However Eun et al reported that 37% of their group of 43 infants discontinued the KD due to complications [6]. Most studies are based on retrospective data, which implies a lower quality assessment of side effects.

For summary of reported side effects in infants see supplementary material [4-9, 52-54].

Table 6 A. Advised clinical monitoring during follow up.

Assessment of KD efficacy by seizure diary and medication review, also any other observed benefits	Every follow up visit.
Assessment of KD tolerance and side effects including questions about bowel function, sleep, behavior and appetite	Every follow up visit.
Weight, height and head circumference	Every follow up visit
Blood and urine testing	As detailed in Table 6B. Tests should be repeated more frequently if show abnormal results or there are other concerns
Renal ultrasound	After 12 months on the KD. As an extra test if clinically indicated by haematuria in 3 consecutive tests or if an infant shows unexplained irritability (at baseline and during KD).
EEG	When clinically indicated.
ECG	At baseline and if clinically indicated.
Dual Energy X-ray Absorptiometry (DEXA)	Due to the limited reference data for this young age group, routine monitoring with DEXA scans is not recommended in infants

Table 6 B. Advised biochemical monitoring during follow up.

Investigation	Frequency of monitoring
<u>Essential :</u>	
<u>Blood:</u> Full blood count	6 weeks, 3 months, 6 months, then every 6 months
Renal profile (includes sodium, potassium, urea, creatinine, bicarbonate and albumin)	6 weeks, 3 months, 6 months, then every 6 months
Liver profile	6 weeks, 3 months, 6 months, then every 6 months
Calcium, phosphate, magnesium	6 weeks, 3 months, 6 months, then every 6 months
Glucose	6 weeks, 3 months, 6 months, then every 6 months
Vitamin D	after 3 months, 6 months, then every 6 months
Lipid profile (repeat with fasting if elevated)	after 3 months, 6 months, then every 6 months
Free and acylcarnitine profile	after 3 months, 6 months, then every 6 months
<u>Urine:</u> calcium: creatinine ratio, haematuria	6 weeks, 3 months, 6 months, then every 6 months
<u>Recommended :</u>	
<u>Blood:</u> Vitamins A, E , B12	6 months, then every 12 months

Zinc, selenium, copper	6 months, then every 12 months
Folate, ferritin	6 months, then every 12 months

6.4 Fine tuning

When the ketosis doesn't reach the adequate range (2-5mmol/l in blood) within 2 weeks after diet initiation and careful calculation, it is important to adjust the diet (ratio) to optimise the diet effect. It is also important to exclude medication, including IV, that may contain significant amounts of glucose or other carbohydrates.

6.5 Weaning

To stimulate oral motor activity and to avoid feeding aversion behavior, solid foods may be introduced at age of 4-6 months (sometimes at 9 months in the event of developmental delay). Combining ketogenic formula with solid food is possible while maintaining the classical diet. Recipes can be calculated based on the original diet ratio (3:1). This will be suitable for most infants (for example vegetable or fruit purees mixed with oil/margarine or fruit with double cream). At the age of 9-12 months when more carbohydrate containing foods are introduced (such as bread, potatoes) a more liberal KD version with a low-dose of MCT is also possible and well tolerated. The amount of MCT is mixed with a (low fat) milk product and gradually increased.

The full MCT KD (50-60 % energy MCT) allows a generous amount of protein and carbohydrates, but is not recommended as it is poorly tolerated in infancy

7. Diet during emergency situations.

The increased risk of hyperketosis should be considered during intercurrent illness. This is caused by reduced energy and carbohydrate intake in combination with elevated metabolism due to illness. Frequent testing of ketosis / blood glucose with use of additional carbohydrate as needed (additional Oral Rehydration Salt (ORS), glucose solution) is then required.

In calculating the allowed quantity of ORS / 24 hours, the carbohydrate level of the individual KD will initially be assumed. This is a deciding factor for the dosage and use of ORS during periods of illness. When the child recovers the KD formula and/or solid foods may be reintroduced gradually.

In a child established on the KD who needs to be nil by mouth and requires hydration intravenously for this or other reasons, solutions containing glucose should be avoided; 0.45% or 0.9% saline or Ringers-lactate should be utilized. Frequent testing of ketosis / blood glucose is required.

If a child has an enteral feeding tube or PEG and is thought to be absorbing, then a liquid KD diet can be utilized as tolerated. Care needs to be given to avoid aspiration. An enteral tube feed can also be utilized in status epilepticus that has failed first and second line therapy [55].

8. Evaluation and discontinuation.

The overall aim of treatment is to reduce, if not control, epileptic seizures. To monitor this, it is important for seizures to be documented in a form of a diary. Further secondary gains may be aimed for such as reduction of AEDs, as well as increased alertness and attention, although neither of these gains can be predicted.

The aim of the treatment in case of infantile spasms (IS) varies according to the course of the disease. This is the most common seizure type in the first year of life. When the KD is used in

IS as first, second or third line treatment, the aim remains to achieve seizure freedom. After one month on KD, a child neurologist should then evaluate the patient to discuss the use of an AED in addition to KD [9]. When the KD is used in resistant IS, the overall aims are similar to the other drug resistant epilepsy syndromes (seizure reduction as well as the reduction of AEDs).

A cognitive or psychomotor improvement is frequently observed. This has been reported by several studies using the KD in infants [4, 7, 9]. This outcome requires further evaluation in the future. The current data are limited by uncontrolled studies with small sample size. The data on cognitive improvement are based on the report of the parents during the clinics or with a questionnaire. The use of validated scales of neurodevelopment or standardized tests that can be repeated to evaluate alertness or attention would permit better assessment in future studies.

8.1 Evaluation period.

A formal evaluation of the effectiveness of the KD should be made by the ketogenic team (including neurologist and dietitian) in discussion with the family at any time dependent on the severity of the epilepsy and number of other treatment options that have previously been tried. Consideration should also be given to tolerance and the parent or caregiver's ability to comply fully with the dietary restrictions.

There is only one study reporting when the seizures improve in responding patients on the KD [56]. This retrospective study evaluated the time to seizure reduction in 118 epilepsy patients who started on the KD of whom 84% had a seizure reduction. The first sign of improvement was observed after a mean time of 5 days (1-65 days). Seventy-five percent had improvement within the first 14 days of the diet and 90% within 23 days [56].

Recommendations: the KD should be maintained for 2-3 months to undoubtedly evaluate efficacy. During this time a degree of fine tuning to the diet may have been required. As mentioned, the delay to control seizures has been described as a prognostic factor in IS. The patient with IS treated by KD as first, second or third treatment (aim of treatment is still seizure freedom) should be evaluated by the child neurologist after one month of KD to consider an additional treatment.

8.2 Discontinuation.

The KD is usually continued for at least 2 years in children who have seen effective seizure control. There is evidence that seizure control can be maintained after a return to a normal diet in children who have a positive response to diet therapy [57]. Children with GLUT 1 deficiency and PDHC deficiency do not usually discontinue the KD as this will be treating the underlying metabolic defect. However, there is evidence that they may tolerate a reduced ratio (with increased carbohydrate intake) in a longer term. In the case of IS, a study randomizing the seizure-free patients to either discontinue the diet in the short-term (8 months) or long term (2 years) showed no difference in the rate of seizure relapse between the two groups [58]. Considering the possible occurrence of side effects including growth consequences, a shorter duration of KD in IS might be considered. Further studies are required to confirm or refute this

Weaning from KD back on to normal diet should be done gradually using a step-wise approach over weeks or months. The longer a child has been on KD the longer the period of withdrawal advised; if seizure-free the process may take 3-4 months. The ketogenic ratio will be slowly reduced, e.g. by 0.25, 0.5 or 1.0 every few days, weeks, or more slowly, e.g. every

month. However, if there has been no benefit from the diet a full wean within 2 weeks is possible, especially in the young infant who needs to move quickly to the next treatment option. Ketone levels can be monitored during this time and once they are no longer present in blood or urine tests the transition to normal diet can be made more quickly. This process can be an anxious time for parents or caregivers who may need reassurance and support. If at any point there is deterioration in seizure control the child can go back to the last ratio used. Concentrated sources of refined carbohydrate should only be reintroduced cautiously once the child is fully established on a normal diet without ill effects.

9. Conclusions and remarks for future research.

These guidelines represent the first international effort to identify commonalities in the clinical use of the KD in infants. All members of the project and review group agreed on most of the major issues in both choosing the best candidates for the KD, pre-diet counseling, supplementation, and the management of children on the KD in regards to nutrition, laboratory values, potential adverse effects, and eventual discontinuation. Areas of variability included choice of initial diet ratio, how to initiate the KD and how to design the nutritional composition of the KD to reach adequate ketosis, with respect to the specific requirements of the infant.

The creation of these recommendations for use in infants encourages safe and effective implementation of the KD in this vulnerable group of patients .

Future research should focus on effects of seizure reduction in specific underlying conditions, how to minimize adverse effects to prevent discontinuation and how to optimize growth of the infant.

10. Disclosure.

The project group was supported financially (travel and hotel costs only) to attend the meeting at the DMIMD 2015 in London. The project group composed of E. van der Louw, T. van den Hurk, E. Neal, S. Auvin and J. H. Cross has built their recommendations based on their own personal view and clinical experience and evidence, with no influence or editorial rights on the output by any company. E. Neal received an unrestricted grant by Nutricia, other members of the project group received no financial support.

Acknowledgements.

The authors thank Prof. Dr. Eric Kossoff, Nicole dos Santos, RD Ketogenic Dietitian, St George Hospital, London, UK and Christine Williams-Dyjur, RD, Pediatric Neurosciences, Ketogenic Diet Program, Alberta Children's Hospital, Canada for their expertise and contribution to the manuscript.

Appendix I

Project group members:

- Elles van der Louw, RD, Pediatric Dietitian, Erasmus University Hospital Sophia Children's Hospital Rotterdam, the Netherlands.
- Dorine van den Hurk, RD, Pediatric Dietitian, Wilhelmina Children's Hospital, University Medical Center Utrecht, the Netherlands.
- Elizabeth Neal, RD MSc PhD, Ketogenic dietitian, Matthews Friends Clinics, Lingfield, UK.
- Prof. Dr. Helen Cross, The Prince of Wales's Chair of Childhood Epilepsy and Honorary Consultant in Paediatric Neurology at UCL Institute of Child Health, Great Ormond Street Hospital for Children NHS Trust, London, UK.
- Prof. Dr. Stéphane Auvin, Pediatric Epilepsy & Child Neurology, Robert-Debré Children Hospital, Paris-Diderot University, Paris, France.

Members of the review group:

- Laura Dority, MS, RD, LD, Ketogenic/Pediatric Dietitian, Medical University of South Carolina, USA.
- Dr. Anastasia Dressler, Universitätsklinik für Kinder- und Jugendheilkunde Pädiatrisches Epilepsiezentrum, Wien.
- Dr. Magdalena Dudzińska, Child Neurologist, Department Department of Children's Neurology Center of Pediatrics and Oncology, Chorzow, Poland.
- Georgiana Fitzsimmons, Ketogenic Dietitian, Great Ormond Street Hospital for Children, London, UK.
- Prof. Dr. Joerg Klepper, Klinikum Aschaffenburg-Alzenau, Germany.

- Bärbel Leiendecker, Pediatric Dietitian, University of Essen, Children's Hospital, Germany.
- Maddalena Marchiò, RD, Pediatric Dietitian, Laboratory of Experimental Epileptology Section of Physiology and Neurosciences Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia
- Nicole dos Santos, Ketogenic Dietitian, St George Hospital, London, UK.
- Lindsey Thompson, Senior Clinical Nutrition Specialist, Children's Mercy Hospital and Clinics, Overland Park, Kansas, USA.
- Christine Williams-Dyjur, RD, Pediatric Neurosciences, Ketogenic Diet Program, Alberta Children's Hospital, Canada.

Additional intake/growth: weekly

Cal monitoring (table 6 a/b)

Food / Urine Monitoring : daily

Abdominal US: after 12 months

WARNING AT INITIATION AND DURING THE DIET

HYPERKETOSIS?

**Rapid breathing,
increased heart rate**

Supplementary data Summary of reported adverse effects of KD in infants.

Study	Infant population	Adverse effects
Nordli et al, 2001 Retrospective review	32 infants < 24 months Mean age KD initiation 14 months	6/32 (19%): Coma due to hypoglycaemia and acidosis post initiation – n=1, Vomiting – n=1, Renal stone – n=1, Gastro-intestinal bleed (erosive oesophagitis from NG tube) – n=1-Hyperlipidaemia – n=1, Ulcerative colitis – n=1
Goyens et al, 2002 Single case report	KD initiated at 13 days in GLUT1 DS neonate	Weight loss and malnutrition associated with low lipase activity, treated with pancreatic enzymes and use of MCT.
Eun et al, 2006 Retrospective review	43 infants aged 6-42 months with infantile spasms Mean age KD initiation 19 months	24/43 (56%): Gastrointestinal disturbances – n=8 (1 within 4 weeks) Serious infectious disease – n=4 Severe dehydration – n=3 (2 within 4 weeks) Pneumonia – n=3 (1 lipoid aspiration, 2 within 4 weeks) Renal stone – n=2, Haematuria with hypercalcuria – n=1 Reflux oesophagitis – n=1, Erosive gastritis – n=1, Fatty liver – n=1
Kossoff et al, 2008 Retrospective review	13 infants <12 months treated with KD as first line for infantile spasms Median age of spasms onset – 5 months	4/13 (31%): Gastro oesophageal reflux –n= 1 Constipation – n=1 Poor tolerance of formula –n= 1 Weight loss –n= 1
Hong et al, 2010 Prospective study	104 infants with infantile spasms Mean age KD initiation 1.2 years	34/104 (33%): Dyslipidaemia – n=17, Constipation – n=7, Gastro oesophageal reflux – n=6, Behavioural problems – n=3, Haematuria – n=3, Diarrhea – n=3, Renal stone – n=3, Acidosis – n=3, Hair thinning – n=2, , Hypercalcaemia – n=2, Dry skin – n=1, Pica – n=1

Numis et al, 2011 Retrospective review	26 infants with infantile spasms Mean age KD initiation 19 months	6/26 (23%): Irritability, lethargy, decreased appetite, persistent hypoglycaemia, renal stone, vitamin D deficiency (numbers not specified)
Pires et al, 2013 Prospective study	17 infants with infantile spasms, 16<12 months Mean age KD initiation 9 months	Weight loss and dyslipidemia (raised triglycerides) in some infants
Kayyali et al, 2014 Prospective study	20 infants with infantile spasms Mean age KD initiation 1.2 years (0.3-2.9 years)	12/20 (60%): Constipation – n=7, Acidosis – n=4, Minor dyslipidemia - n=3, Diarrhea – n=1, Urinary sediment- n=1
Dressler et al, 2015 Retrospective study	58 infants < 18 months, (42 <9 months) Mean age KD initiation 0.68 years (0.15-1.5 years)	29/58 (50%): Carnitine deficiency – n=4, kidney stones – n=3, Minor dyslipidemia - n=21 Weight gain– n=1, Growth deficiency- n=3, high cholesterol – n=2
