ABSTRACT

Three-dimensional (3D) printing technology in congenital cardiology and cardiac surgery has experienced a rapid development over the last decade. In presence of complex cardiac and extra-cardiac anatomies, the creation of a physical, patient-specific model is attractive to most clinicians. However, at the present time, there is still a lack of strong scientific evidence of the benefit of 3D models in clinical practice and only qualitative evaluation of the models has been used to investigate their clinical use. 3D models can be printed in rigid or flexible materials, and the original size can be augmented depending on the application the models are needed for. The most common applications of 3D models at present include procedural planning of complex surgical or interventional cases, in vitro simulation for research purposes, training and communication with patients and families. The aim of this pictorial review is to describe the basic principles of this technology and present its current and future applications.

INTRODUCTION

The possibility to create physical, patient-specific models by means of three-dimension (3D) printing is appealing when dealing with complex anatomies in paediatric and adult patients with congenital heart disease (CHD). Patients with CHD are regularly monitored with imaging, yet often a single imaging modality is not sufficient to fully appreciate the complexity of cardiac anatomy, physiology and extra cardiac spatial relationships. Moreover, these patients frequently undergo multiple surgeries with implantation of devices, increasing their complexity and resulting in unique anatomical variations. For these reasons, 3D printing has proved useful in congenital cardiology and cardiac surgery.1,2

Experts in non-invasive cardiovascular imaging have a great ability to understand cardiac anatomy from traditional cross-sectional images even in the presence of complex CHD. However, holding a physical 3D reconstruction of a patient’s anatomy can augment the understanding of spatial relationships and of the real dimensions of both cardiac and extra cardiac structures. Furthermore, 3D printing is likely to be even more helpful for physicians with less expertise in analysing and interpreting cardiovascular images, for instance cardiac surgeons and interventional cardiologists.

Generally, what can be imaged in 3D can be printed in 3D, so using 3D images from CT, MRI or 3D echocardiography as inputs, it is possible to produce 3D printed models of the entire heart or of a specific region of interest (Figure 1). Most commonly, CT images or 3D MRI images (whole-heart MRI or contrast-enhance MR angiography) are used to produce 3D models. Through an accurate post-processing analysis, or “segmentation” process, the images are transformed into 3D surface files (.stl) and sent to the printer (Figure 2). ECG-gated 3D balanced steady state free precession images usually have adequate quality to perform the segmentation process, however mobile structures such as valve leaflets cannot be adequately seen and segmented. Cardiac MRI has the advantage of being radiation free, however acquisition time are long and might not be well tolerated in paediatric patients. The use of current multidetector cardiac CT scans and non-ECG gated acquisitions allow to reduce the radiation exposure, maintaining a good spatial resolution. The final result will depend greatly on the quality of the input images.
and on the operator performing the segmentation, who needs to be able to fully understand the cardiac anatomy. This suggests either the need to train a 3D printing operator for specific cardiac applications or the importance of close liaison between bioengineers and clinicians when creating a model.

A variety of materials can be chosen for printing. Compliant rubber-like material or silicone are likely preferable for surgical practice, enabling cutting into the model, but are typically more expensive (Figure 3). The cost of the model however depends also on its size, and small 3D models are cheaper because a smaller amount of material is used for printing (Figure 4). Rigid materials (e.g. SLA resins) can be used for educational or communication purposes. Indeed, 3D models have been used for different purposes in CHD, including procedural planning, research applications, training and doctor-patient communication (Figure 5).

**PROcedural Planning**

Patient-specific 3D printed models can be used to plan surgical and percutaneous interventions (Figures 6 and 7). Case reports and small case series have suggested that 3D printed models facilitate the decision-making process in complex cases. However, only qualitative analysis of the models by means of satisfaction questionnaires has so far been used to evaluate their benefit. A recent multicentre prospective study aimed to evaluate the impact of 3D printing models in planning 40 complex CHD surgeries, providing surgeons with a 3D printed model after a first multidisciplinary discussion and registering a change in surgical strategy in 19/40 cases. As for other smaller series, the main limitation of the study is that measurable outcomes, e.g. cross-clamp time, bypass time, days of hospital admission or mid- and long-term follow-up information, were not included. 3D printing has also been used successfully for percutaneous procedures, for instance adopting 3D printed models of right ventricular outflow tract in patients with pulmonary valve regurgitation as a tool to aid clinicians in selecting patients eligible for percutaneous pulmonary valve implantation. Meaningful clinical applications include:

1. **Visualization of the size of the pathological structures in presence of rare congenital abnormalities** (Figure 8).
2. **Three-dimensional visualization of intra cardiac structures** (Figure 9).

Figure 3. Depending on the application of the model, different materials can be used. In this figure, the same heart of a 1-year-old patient with double outlet right ventricle was printed in (a) Nylon; (b) Transparent resin (c) Compliant rubber-like material and (d) Compliant rubber-like material black.
(3) Understanding of the spatial relationship of the great vessels in cases of complex CHD, particularly in post surgical anatomies (Figure 10).6

RESEARCH APPLICATIONS

Patient-specific 3D models can be incorporated in the context of experimental set-ups for research applications (Figure 11). Models also represent useful tools to validate computational simulations, with several studies reporting good correlations between patient-specific model simulations \textit{in vitro} and \textit{in silico} when assessing cardiovascular hydrodynamics in CHD,7 also accounting for the presence of devices, such as percutaneous valves.8

Figure 5. Application of 3D models in congenital cardiology and cardiac surgery. Biomedical engineers use the physical model to create experimental set ups and test hydrodynamic conditions in patient specific settings; these setups are used also to validate computation models. Physical models are used for clinical purposes in surgical planning and decision-making of complex procedures, as well as to test new application of devices to patient specific anatomy. Medical students and trainee can benefit from the use of three-dimensional models during cardiac morphology courses as well as cardiac surgeon from practicing complex procedures. Comparing to medical images, physical models are much easier to understand for patients and parents.

Figure 6. Patient specific model was used to test a range of devices potentially suitable for the patient case, checking geometrical anchoring and suitability to patient anatomy.

TRAINING

Congenital heart disease patients are particularly challenging for trainees and fellows in cardiac surgery, with limited opportunity to practice without endangering paediatric patients. 3D models printed with flexible materials have been proposed as a tool for practicing surgical procedures (Figure 12). Models were found useful although the elasticity of the material was reported as different from real myocardial tissue by the surgeons.9 Clinical staff can benefit from additional training with 3D models for increasing the appreciation of CHD anatomy after cardiac surgery, e.g. during training courses for cardiac nurses.10 Furthermore, 3D models present advantages over specimens in terms of their cost, ease of reproducibility and conservation/storage, or can be used in conjunction with specimens providing...
Figure 8. A 14-year-old female patient who was referred for cardiac CT after echocardiography showing prominent coronary artery flow, suggesting presence of fistula or anomalous artery connection. CT images confirmed the diagnosis of anomalous origin of the circumflex coronary artery from right pulmonary artery (a and b). 3D model (c) was manufactured (d) for better understanding of coronary anatomy and dimensions.

Figure 9. Complex congenital case: double outlet right ventricle with transposition of the great arteries and non-committed VSD, repaired with LV to aorta baffle presenting with symptoms of left ventricular outflow tract (LVOT) obstruction. Model manufactured on clinical request for assessment of LVOT anatomy. The yellow arrow shows the LV to aorta intracardiac baffle. (a,b) Two views from CT data, (c) 3D reconstruction, (d) 3D-printed model.

Figure 10. Complex congenital case: A 11-year-old patient truncus arteriosus presenting with conduit and pulmonary stenosis. The model was used to assess the relationship between the aorta and the pulmonary arteries in order to plan the surgery. (a) CT images showing the position of the branch pulmonary arteries and the aorta. (b) Segmentation process to create the 3D model (highlighted in red); (c) 3D reconstruction used as input file to create the 3D model; (d) 3D model printed in white resin.

Beyond the clinic, 3D models have also been used to bring together art and medicine to foster patients and public involvement and engagement and explore novel stimulating ways of portraying the complexity of cardiovascular anatomy in the presence of CHD (Figure 15).

Recommendations for use in clinical practice
There are no current recommendations or guidelines for standardised use of 3D models in congenital cardiology and cardiac surgery. Current use in clinical practice includes ad hoc application for planning or practicing complex procedures. The use of 3D models is currently limited to very complex cases with unique cardiac anatomy, e.g. patients with double outlet right ventricle with non-committed VSD. Small studies and case series have described the use of the 3D models in clinical practice; however,
it is very difficult to correlate their use with clinical outcomes, because of the small populations investigated so far and the uniqueness of each patient. The outcomes of on-going research focusing on scientific evidences of 3D model’s usefulness will likely influence the development of clinical recommendations.

Figure 12. In this example, a cardiac surgery fellow is practicing on the creation of an intracardiac baffle from the VSD to the aorta in a patient with DORV using a 3D model printed in compliant rubber-like material.

Figure 13. The use of 3D model is particularly valuable for education in congenital cardiology and cardiac surgery. Patient anatomies are often unique and it is difficult to capture the wide range of anatomical variations that occur in the context of the same cardiac malformation. In this example, four patient specific virtual 3D models of double outlet right ventricle are imaged. (From 3D library at http://www.ucl.ac.uk/cardiac-engineering/research/library-of-3d-anatomies).

Figure 14. Example of a 3D model of an adult patient with transposition of the great arteries who underwent Mustard procedure. The model was printed with a off-white plaster powder on a Projet 660 printer, and was then used during a workshop with the patient.

Figure 15. Making the Invisible Visible II, Sofie Layton, 2018 (detail). Installation including 3D printed hearts of paediatric and adult patients with congenital heart disease, and with soundscape by Jules Maxwell. As part of “The Heart of the Matter” exhibition (www.insidetheheart.org)

FUTURE PERSPECTIVES
Novel techniques that allow automatic segmentation of complex cardiac and extra cardiac structures (e.g. atlas-based segmentation
Secondly, a relatively long time is required to produce a model, and new surgical techniques, also beyond CHD, whilst the combination of 3D models with tissue engineering could lead to bioprinting patient-specific grafts and heart valves.\textsuperscript{14,15}

**CONCLUSION**

All imaging modalities (CT, MRI and echocardiography) have developed towards 3D reconstruction techniques, implicitly suggesting the clinical need of going beyond the traditional 2D evaluation of cardiac structures and better appreciating CHD anatomy. Despite its attractiveness, scientific evidence of the usefulness of 3D printing in CHD there is still lacking, and several factors still prevent its becoming widely available. From the perspective of different stakeholders: a cost-benefit analysis, are urgently needed to prove the real impact of this technology in the management of patients with CHD.
