Abstract The performance of the missing transverse momentum (E_T^{miss}) reconstruction with the ATLAS detector is evaluated using data collected in proton–proton collisions at the LHC at a centre-of-mass energy of 13 TeV in 2015. To reconstruct E_T^{miss} , fully calibrated electrons, muons, photons, hadronically decaying τ -leptons, and jets reconstructed from calorimeter energy deposits and charged-particle tracks are used. These are combined with the soft hadronic activity measured by reconstructed charged-particle tracks not associated with the hard objects. Possible double counting of contributions from reconstructed charged-particle tracks from the inner detector, energy deposits in the calorimeter, and reconstructed muons from the muon spectrometer is avoided by applying a signal ambiguity resolution procedure which rejects already used signals when combining the various E_T^{miss} contributions. The individual terms as well as the overall reconstructed E_T^{miss} are evaluated with various performance metrics for scale (linearity), resolution, and sensitivity to the data-taking conditions. The method developed to determine the systematic uncertainties of the E_T^{miss} scale and resolution is discussed. Results are shown based on the full 2015 data sample corresponding to an integrated luminosity of 3.2 fb^{-1} .

1 Introduction

The missing transverse momentum (E_T^{miss}) is an important observable serving as an experimental proxy for the transverse momentum carried by undetected particles produced in proton–proton (pp) collisions measured with the ATLAS detector [1] at the Large Hadron Collider (LHC). It is reconstructed from the signals of detected particles in the final state. A value incompatible with zero may indicate not only the production of Standard Model (SM) neutrinos but also the production of new particles suggested in models for physics beyond the SM that escape the ATLAS detector without being detected. The reconstruction of E_T^{miss} is challenging because it involves all detector subsystems and requires the most complete and unambiguous representation of the hard interaction of interest by calorimeter and tracking signals. This representation is obscured by limitations introduced by the detector acceptance and by signals and signal remnants from additional pp interactions occurring in the same, previous and subsequent LHC bunch crossings (pile-up) relative to the triggered hard-scattering. ATLAS has developed successful strategies for a high-quality E_T^{miss} reconstruction focussing on the minimisation of effects introduced by pile-up for the data recorded between 2010 and 2012 (LHC Run 1) [2,3]. These approaches are the basis for the E_T^{miss} reconstruction developed for the data collected in 2015 (LHC Run 2) that is described in this paper, together with results from performance evaluations and the determination of systematic uncertainties.

This paper is organised as follows. The subsystems forming the ATLAS detector are described in Sect. 2. The E_T^{miss} reconstruction is discussed in Sect. 3. The extraction of the data samples and the generation of the Monte Carlo (MC) simulation samples are presented in Sect. 4. The event selection is outlined in Sect. 5, followed by results for E_T^{miss} performance in Sect. 6. Section 7 comprises a discussion of methods used to determine systematic uncertainties associated with the E_T^{miss} measurement, and the presentation of the corresponding results. Section 8 describes variations of the E_T^{miss} reconstruction using calorimeter signals for the soft hadronic event activity, or reconstructed charged-particle tracks only. The paper concludes with a summary and outlook in Sect. 9. The nomenclature and conventions used by ATLAS for E_T^{miss} -related variables and descriptors can be found in Appendix A, while the composition of E_T^{miss} reconstruction variants is presented in Appendix B. An evaluation of the effect of alternative jet selections on the E_T^{miss} reconstruction performance is given in Appendix C.

2 ATLAS detector

The ATLAS experiment at the LHC features a multi-purpose particle detector with a forward–backward symmetric cylindrical geometry and a nearly full (4π) coverage in solid angle.¹ It consists of an inner detector (ID) tracking system in a 2 T axial magnetic field provided by a superconducting solenoid. The solenoid is surrounded by electromagnetic and hadronic calorimeters, and a muon spectrometer (MS). The ID covers the pseudorapidity range $|\eta| < 2.5$, and consists of a silicon pixel detector, a silicon microstrip detector and a transition radiation tracker for $|\eta| < 2.0$. During the LHC shutdown between Run 1 and Run 2, a new tracking layer, known as the insertable B-layer [4], was added between the previous innermost pixel layer and a new, narrower beam pipe.

The high-granularity lead/liquid-argon (LAr) sampling electromagnetic calorimeter covers the region $|\eta| < 3.2$. The regions $|\eta| < 1.37$ and $1.5 < |\eta| < 1.8$ are instrumented with presamplers in front of the LAr calorimeter in the same cryostat. A steel/scintillator-tile calorimeter (Tile) provides hadronic coverage in the central pseudorapidity range $|\eta| < 1.7$. LAr technology is also used for the hadronic calorimeters in the endcap region $1.5 < |\eta| < 3.2$ and for electromagnetic and hadronic energy measurements in the forward calorimeters covering $3.2 < |\eta| < 4.9$.

The MS surrounds the calorimeters. It consists of three large superconducting air-core toroidal magnets, precision tracking chambers providing precise muon tracking out to $|\eta| = 2.7$, and fast detectors for triggering in the region $|\eta| < 2.4$.

A two-level trigger system is used to select events [5]. A low-level hardware trigger reduces the data rate, and a high-level software trigger selects events with interesting final states. More details of the ATLAS detector can be found in Ref. [1].

3 E_T^{miss} reconstruction

The reconstructed E_T^{miss} in ATLAS is characterised by two contributions. The first one is from the *hard-event* signals comprising fully reconstructed and calibrated particles and jets (hard objects). The reconstructed particles are electrons, photons, τ -leptons, and muons. While muons are recon-

¹ ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the centre of the detector and the z -axis along the beam pipe. The x -axis points from the IP to the centre of the LHC ring, and the y -axis points upwards. Cylindrical coordinates (r, ϕ) are used in the transverse plane, ϕ being the azimuthal angle around the z -axis. The pseudorapidity is defined in terms of the polar angle θ as $\eta = -\ln \tan(\theta/2)$. Angular distance is measured in units of $\Delta R \equiv \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$.

structed from ID and MS tracks, electrons and τ -leptons are identified combining calorimeter signals with tracking information. Photons and jets are principally reconstructed from calorimeter signals, with possible signal refinements from reconstructed tracks. The second contribution to E_T^{miss} is from the *soft-event* signals consisting of reconstructed charged-particle tracks (soft signals) associated with the hard-scatter vertex defined in Appendix A but not with the hard objects.

ATLAS carries out a dedicated reconstruction procedure for each kind of particle as well as for jets, casting a particle or jet hypothesis on the origin of (a group of) detector signals. These procedures are independent of one another. This means that e.g. the same calorimeter signal used to reconstruct an electron is likely also used to reconstruct a jet, thus potentially introducing double counting of the same signal when reconstructing E_T^{miss} . This issue is addressed by the explicit *signal ambiguity resolution* in the object-based E_T^{miss} reconstruction originally introduced in Refs. [2, 3], and by its 2015 implementation described in Sects. 3.1 and 3.2.

Additional options for the set of signals used to reconstruct E_T^{miss} are available and discussed in detail in Sect. 8. One of these alternative options is the calorimeter-based E_T^{miss} reconstruction discussed in Sect. 8.1, which uses a soft event built from clusters of topologically connected calorimeter cells (topo-clusters) [6]. Another option is the track-based missing transverse momentum, which differs from E_T^{miss} only in the use of tracks in place of jets. It is described in more detail in Sect. 8.2.

3.1 E_T^{miss} basics

The missing transverse momentum reconstruction provides a set of observables constructed from the components $p_{x(y)}$ of the transverse momentum vectors (\mathbf{p}_T) of the various contributions. The missing transverse momentum components $E_{x(y)}^{\text{miss}}$ serve as the basic input for most of these observables. They are given by

$$E_{x(y)}^{\text{miss}} = - \sum_{i \in \{\text{hard objects}\}} p_{x(y),i} - \sum_{j \in \{\text{soft signals}\}} p_{x(y),j}. \quad (1)$$

The set of observables constructed from $E_{x(y)}^{\text{miss}}$ is

$$\mathbf{E}_T^{\text{miss}} = (E_x^{\text{miss}}, E_y^{\text{miss}}), \quad (2)$$

$$E_T^{\text{miss}} = |\mathbf{E}_T^{\text{miss}}| = \sqrt{(E_x^{\text{miss}})^2 + (E_y^{\text{miss}})^2}, \quad (3)$$

$$\phi^{\text{miss}} = \tan^{-1}(E_y^{\text{miss}}/E_x^{\text{miss}}). \quad (4)$$

The vector $\mathbf{E}_T^{\text{miss}}$ provides the amount of the missing transverse momentum via its magnitude E_T^{miss} , and its direction in the transverse plane in terms of the azimuthal angle ϕ^{miss} . Consequently, E_T^{miss} is non-negative by definition. However, in an experimental environment where not all relevant p_T

from the hard-scatter interaction can be reconstructed and used in Eq. (1), and the reconstructed p_T from each contribution is affected by the limited resolution of the detector, an *observation bias* towards non-vanishing values for E_T^{miss} is introduced even for final states without genuine missing transverse momentum generated by undetectable particles.

The scalar sum of all transverse momenta ($p_T = |\mathbf{p}_T|$) from the objects contributing to E_T^{miss} reconstruction is given by

$$\Sigma E_T = \sum_{i \in \{\text{hard objects}\}} p_{T,i} + \sum_{j \in \{\text{soft signals}\}} p_{T,j}. \quad (5)$$

In the context of E_T^{miss} reconstruction, ΣE_T is calculated in addition to the sum given in Eq. (1), and the derived quantities defining E_T^{miss} given in Eqs. (2)–(4). It provides a useful overall scale for evaluating the hardness of the hard-scatter event in the transverse plane, and thus provides a measure for the event activity in physics analyses and E_T^{miss} reconstruction performance studies.

In the calculation of $E_{x(y)}^{\text{miss}}$ and ΣE_T the contributing objects need to be reconstructed from mutually exclusive detector signals. This rule avoids multiple inclusions of the same signal in all constructed observables. The implementation of this rule in terms of the signal ambiguity resolution requires the definition of a sequence for selected contributions, in addition to a rejection mechanism based on common signal usage between different objects. Similarly to the analysis presented in Ref. [3], the most commonly used order for the E_T^{miss} reconstruction sequence for the hard-object contribution starts with electrons (e), followed by photons (γ), then hadronically decaying τ -leptons (τ_{had}), and finally jets. Muons (μ) are principally reconstructed from ID and MS tracks alone, with corrections based on their energy loss in the calorimeter, leading to little or no signal overlap with the other reconstructed particles in the calorimeter.

In the sequence discussed here, all electrons passing the selection enter the E_T^{miss} reconstruction first. The lower-priority reconstructed particles (γ , τ_{had}) are fully rejected if they share their calorimeter signal with a higher-priority object that has already entered the E_T^{miss} reconstruction. Muons experience energy loss in the calorimeters, but only non-isolated muons overlap with other hard objects, most likely jets or τ -leptons. In this case the muon’s energy deposit in the calorimeter cannot be separated from the overlapping jet-like objects with the required precision, and the calorimeter-signal-overlap resolution based on the shared use of topo-clusters cannot be applied. A discussion of the treatment of isolated and non-isolated muons is given in Sect. 3.3.4.

Generally, jets are rejected if they overlap with accepted higher-priority particles. To avoid signal losses for E_T^{miss} reconstruction in the case of partial or marginal overlap, and

to suppress the accidental inclusion of jets reconstructed from calorimeter signals from large muon energy losses or pile-up, the more refined overlap resolution strategies described in Sects. 3.3.5 and 3.3.6 are applied.

Excluding ID tracks associated with any of the accepted hard objects contributing to E_T^{miss} , ID tracks from the hard-scatter collision vertex are used to construct the soft-event signal for the results presented in this paper.

3.2 E_T^{miss} terms

Particle and jet selections in a given analysis should be reflected in E_T^{miss} and ΣE_T for a consistent interpretation of a given event. Each reconstructed particle and jet has its own dedicated calibration translating the detector signals into a fully corrected four-momentum. This means that e.g. rejecting certain electrons in a given analysis can change both E_T^{miss} and ΣE_T , if the corresponding calorimeter signal is included and calibrated as a jet or a significant part of a jet. This also means that systematic uncertainties for the different particles can be consistently propagated to E_T^{miss} . The applied selections are presented in Sect. 3.3, and summarised in Table 1.

In ATLAS the flexibility needed to recalculate E_T^{miss} and ΣE_T under changing analysis requirements for the same event is implemented using dedicated variables corresponding to specific object contributions. In this approach the full $\mathbf{E}_T^{\text{miss}}$ is the vectorial sum of missing transverse momentum terms $\mathbf{E}_T^{\text{miss},p}$, with $p \in \{e, \gamma, \tau_{\text{had}}, \mu, \text{jet}\}$ reconstructed from the $\mathbf{p}_T = (p_x, p_y)$ of accepted particles and jets, and the corresponding soft term $\mathbf{E}_T^{\text{miss,soft}}$ from the soft-event signals introduced in Sect. 3.1 and further specified in Sect. 3.4. This yields²

$$\mathbf{E}_T^{\text{miss}} = - \underbrace{\sum_{\text{selected electrons}} \mathbf{p}_T^e}_{\mathbf{E}_T^{\text{miss},e}} - \underbrace{\sum_{\text{accepted photons}} \mathbf{p}_T^\gamma}_{\mathbf{E}_T^{\text{miss},\gamma}} - \underbrace{\sum_{\text{accepted } \tau\text{-leptons}} \mathbf{p}_T^{\tau_{\text{had}}}}_{\mathbf{E}_T^{\text{miss},\tau_{\text{had}}}} - \underbrace{\sum_{\text{selected muons}} \mathbf{p}_T^\mu}_{\mathbf{E}_T^{\text{miss},\mu}} - \underbrace{\sum_{\text{accepted jets}} \mathbf{p}_T^{\text{jet}}}_{\mathbf{E}_T^{\text{miss,jet}}} - \underbrace{\sum_{\text{unused tracks}} \mathbf{p}_T^{\text{track}}}_{\mathbf{E}_T^{\text{miss,soft}}}. \tag{6}$$

hardterm softterm

The E_T^{miss} and ϕ^{miss} observables can be constructed according to Eqs. (3) and (4), respectively, for the overall missing transverse momentum (from $\mathbf{E}_T^{\text{miss}}$) as well as for each individual term indicated in Eq. (6). In the priority-ordered reconstruction sequence for E_T^{miss} , contributions are defined by a combination of analysis-dependent selections and a possible rejection due to the applied signal ambiguity resolution.

² In this formula the notion of *selected*, which is only applicable to electrons and muons, means that the choice of reconstructed particles is purely given by a set of criteria similar to those given in Sects. 3.3.1 and 3.3.4, respectively, with possible modifications imposed by a given analysis. The notion of *accepted* indicates a modification of the set of initially selected objects imposed by the signal ambiguity resolution.

The muon and electron contributions are typically not subjected to the signal overlap resolution and are thus exclusively defined by the selection requirements. Unused tracks in Eq. (6) refers to those tracks associated with the hard-scatter vertex but not with any hard object. Neutral particle signals from the calorimeter suffer from significant contributions from pile-up and are not included in the soft term.

Correspondingly, ΣE_T is calculated from the scalar sums of the transverse momenta of hard objects entering the E_T^{miss} reconstruction and the soft term,

$$\begin{aligned} \Sigma E_T &= \underbrace{\sum_{\text{selected electrons}} p_T^e + \sum_{\text{accepted photons}} p_T^\gamma + \sum_{\text{accepted } \tau\text{-leptons}} p_T^{\tau_{\text{had}}} + \sum_{\text{selected muons}} p_T^\mu + \sum_{\text{accepted jets}} p_T^{\text{jet}}}_{\text{hardterm}} \\ &+ \underbrace{\sum_{\text{unused tracks}} p_T^{\text{track}}}_{\text{softterm}}. \end{aligned} \tag{7}$$

The hard term in both E_T^{miss} and ΣE_T is characterised by little dependence on pile-up, as it includes only fully calibrated objects, where the calibration includes a pile-up correction and objects tagged as originating from pile-up are removed. The particular choice of using only tracks from the hard-scatter vertex for the soft term strongly suppresses pile-up contributions to this term as well. The observed residual pile-up dependencies are discussed with the performance results shown in Sect. 6.

3.3 Object selection

The following selections are applied to reconstructed particles and jets used for the performance evaluations presented

in Sects. 6–8. Generally, these selections require refinements to achieve optimal E_T^{miss} reconstruction performance in the context of a given physics analysis, and the selections performed in this study are an example set of criteria.

3.3.1 Electron selection

Reconstructed electrons are selected on the basis of their shower shapes in the calorimeter and how well their calorimeter cell clusters are matched to ID tracks [7]. Both are evaluated in a combined likelihood-based approach [8]. Electrons with at least medium reconstruction quality are selected. They are calibrated using the default calibration given in

Table 1 Overview of the contributions to E_T^{miss} and ΣE_T from hard objects such as electrons (e), photons (γ), hadronically decaying τ -leptons (τ_{had}), muons (μ), and jets, together with the signals for the soft term. The configuration shown is the one used as reference for the performance evaluations presented in this paper. The table is ordered descending in priority \mathbb{P} of consideration for E_T^{miss} reconstruction, with (1) being the first and (5) being the last calculated hard-object contri-

bution. The soft-event contribution is constructed at the lowest priority (6), after all hard objects are considered. The transverse (longitudinal) impact parameter d_0 ($z_0 \sin(\theta)$) used to select the ID tracks contributing to $E_T^{\text{miss,soft}}$ and ΣE_T^{soft} in $\mathbb{P} = (6)$ is measured relative to the hard-scatter vertex. All variables are explained in Sect. 3.2. The angular distance ΔR between objects is defined as $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$

\mathbb{P}	Objects contributing to E_T^{miss} and ΣE_T			
	Type	Selections	Variables	Comments
(1)	e	$ \eta < 1.37$ or $1.52 < \eta < 2.47$ $p_T > 10 \text{ GeV}$	$E_T^{\text{miss},e}$ ΣE_T^e	All e^\pm passing medium reconstruction quality and kinematic selections
(2)	γ	$ \eta < 1.37$ or $1.52 < \eta < 2.47$ $p_T > 25 \text{ GeV}$	$E_T^{\text{miss},\gamma}$ ΣE_T^γ	All γ passing tight quality and kinematic selections in reconstruction, and without signal overlap with (1)
(3)	τ_{had}	$ \eta < 1.37$ or $1.52 < \eta < 2.47$ $p_T > 20 \text{ GeV}$	$E_T^{\text{miss},\tau_{\text{had}}}$ $\Sigma E_T^{\tau_{\text{had}}}$	All τ_{had} passing medium reconstruction quality and kinematic selections, and without signal overlap with (1) and (2)
(4)	μ	$ \eta < 2.7$ $p_T > 10 \text{ GeV}$	$E_T^{\text{miss},\mu}$ ΣE_T^μ	All μ passing medium quality and kinematic selections in reconstruction; for the discussion of the μ -jet overlap removal see Sect. 3.3.6
(5)	Jet	$ \eta < 4.5$ $p_T > 60 \text{ GeV}$ _____ or _____ $2.4 < \eta < 4.5$ $20 \text{ GeV} < p_T < 60 \text{ GeV}$ _____ or _____ $ \eta < 2.4$ $20 \text{ GeV} < p_T < 60 \text{ GeV}$ $JVT > 0.59$	$E_T^{\text{miss,jet}}$ ΣE_T^{jet}	All jets passing reconstruction quality (jet cleaning) and kinematic selections, and without signal overlap ^a with (1)–(3); for the dedicated overlap removal strategy with μ from (4) see Sect. 3.3.6
(6)	ID track	$p_T > 400 \text{ MeV}$ $ d_0 < 1.5 \text{ mm}$ $ z_0 \sin(\theta) < 1.5 \text{ mm}$ $\Delta R(\text{track}, e - / \gamma \text{cluster}) > 0.05$ $\Delta R(\text{track}, \tau_{\text{had}}) > 0.2$	$E_T^{\text{miss,soft}}$ ΣE_T^{soft}	All ID tracks from the hard-scatter vertex passing reconstruction quality and kinematic selections, and not associated with any particle from (1), (3) or (4), or ghost-associated with a jet from (5)

^aWhile for single reconstructed particles no overlap is accepted at all, jets with a signal overlap fraction $\kappa_E < 50\%$ can still contribute their associated tracks to $E_T^{\text{miss,soft}}$ if those pass the selections for $\mathbb{P} = (6)$, as discussed in Sect. 3.3.5. The definition of κ_E is given in Eq. (8)

Ref. [7]. To be considered for E_T^{miss} reconstruction, electrons passing the reconstruction quality requirements are in addition required to have $p_T > 10 \text{ GeV}$ and $|\eta| < 1.37$ or $1.52 < |\eta| < 2.47$, to avoid the transition region between the central and endcap electromagnetic calorimeters. Any energy

deposit by electrons within $1.37 < |\eta| < 1.52$ is likely reconstructed as a jet and enters the E_T^{miss} reconstruction as such, if this jet meets the corresponding selection criteria discussed in Sect. 3.3.5.

3.3.2 Photon selection

The identification and reconstruction of photons exploits the distinctive evolution of their electromagnetic showers in the calorimeters [9]. Photons are selected and calibrated using the tight selection criteria given in Ref. [7]. In addition to the reconstruction quality requirements, photons must have $p_T > 25$ GeV and $|\eta| < 1.37$ or $1.52 < |\eta| < 2.37$ to be included in the E_T^{miss} reconstruction. Similarly to electrons, photons emitted within $1.37 < |\eta| < 1.52$ may contribute to E_T^{miss} as a jet.

3.3.3 τ -Lepton selection

Hadronically decaying τ -leptons are reconstructed from narrow jets with low associated track multiplicities [10]. Candidates must pass the medium quality selection given in Ref. [11], and in addition have $p_T > 20$ GeV and $|\eta| < 1.37$ or $1.52 < |\eta| < 2.47$. Any τ -lepton not satisfying these τ -identification criteria may contribute to E_T^{miss} when passing the jet selection.

3.3.4 Muon selection

Muons are reconstructed within $|\eta| < 2.5$ employing a combined MS and ID track fit. Outside of the ID coverage, muons are reconstructed within $2.5 < |\eta| < 2.7$ from a track fit to MS track segments alone. Muons are further selected for E_T^{miss} reconstruction by requiring the medium reconstruction quality defined in Ref. [12], $p_T > 10$ GeV, and an association with the hard-scatter vertex for those within $|\eta| < 2.5$.

3.3.5 Jet selection

Jets are reconstructed from clusters of topologically connected calorimeter cells (topo-clusters), described in Ref. [6]. The topo-clusters are calibrated at the electromagnetic (EM) energy scale.³ The anti- k_t algorithm [13], as provided by the FASTJET toolkit [14], is employed with a radius parameter $R = 0.4$ to form jets from these topo-clusters. The jets are fully calibrated using the EM+JES scheme [15] including a correction for pile-up [16]. They are required to have $p_T > 20$ GeV after the full calibration. The jet contribution to E_T^{miss} and ΣE_T is primarily defined by the signal ambiguity resolution.

Jets not rejected at that stage are further filtered using a tagging algorithm to select hard-scatter jets (“jet vertex tagging”) [16]. This algorithm provides the jet vertex tagger

variable JVT, ranging from 0 (pile-up-like) to 1 (hard-scatter-like), for each jet with matched tracks.⁴ The matching of tracks with jets is done by *ghost association*, where tracks are clustered as *ghost particles* into the jet, as described in Ref. [3] and based on the approach outlined in Ref. [17].

The overlap resolution can result in a partial overlap of the jet with an electron or photon, in terms of the fraction of common signals contributing to the respective reconstructed energy. This is measured by the ratio κ_E of the electron(photon) energy $E_{e(\gamma)}^{\text{EM}}$ to the jet energy $E_{\text{jet}}^{\text{EM}}$,

$$\kappa_E = \frac{E_{e(\gamma)}^{\text{EM}}}{E_{\text{jet}}^{\text{EM}}}, \quad (8)$$

with both energies calibrated at the EM scale. In the case of $\kappa_E \leq 50\%$, the jet is included in E_T^{miss} reconstruction, with its p_T scaled by $1 - \kappa_E$. For $\kappa_E > 50\%$, only the tracks associated with the jet, excluding the track(s) associated with the overlapping particle if any, contribute to the soft term as discussed in Sect. 3.4.

Jets not rejected by the signal ambiguity resolution and with $p_T > 20$ GeV and $|\eta| > 2.4$, or with $p_T \geq 60$ GeV and $|\eta| < 4.5$, are always accepted for E_T^{miss} reconstruction. Jets reconstructed with $20 \text{ GeV} < p_T < 60 \text{ GeV}$ and $|\eta| < 2.4$ are only accepted if they are tagged by $\text{JVT} > 0.59$. In both cases, the jet p_T thresholds are applied to the jet p_T before applying the κ_E correction. Additional configurations for selecting jets used in E_T^{miss} reconstruction are discussed in Appendix A, together with the effect of the variation of these selection criteria on the E_T^{miss} reconstruction performance.

3.3.6 Muon overlap with jets

Jets overlapping with a reconstructed muon affect the E_T^{miss} reconstruction in a manner that depends on their origin. If these jets represent a significant (*catastrophic*) energy loss along the path of the muon through the calorimeter, or if they are pile-up jets tagged by JVT as originating from the hard-scatter interaction due to the muon ID track, they need to be rejected for E_T^{miss} reconstruction. On the other hand, jets reconstructed from final state radiation (FSR) off the muon need to be included into E_T^{miss} reconstruction.

In all cases, the muon–jet overlap is determined by ghost-associating the muon with the jet. For this, each muon enters the jet clustering as ghost particle with infinitesimal small momentum, together with the EM-scale topo-clusters from the calorimeter. If a given ghost particle becomes part of a jet, the corresponding muon is considered overlapping with this

³ On this scale the energy deposited in the calorimeter by electrons and photons is represented well. The hadron signal at the EM scale is not corrected for the non-compensating signal features of the ATLAS calorimeters.

⁴ In the calculation of JVT the total amount of p_T carried by tracks from the hard-scatter vertex matched to the given jet is related to the total amount of p_T carried by all matched tracks, among other inputs, to tag jets from the hard-scatter interaction.

jet. This procedure is very similar to the track associations with jets mentioned in Sect. 3.3.5.

Tagging jets using JVT efficiently retains those from the hard-scatter vertex for E_T^{miss} reconstruction and rejects jets generated by pile-up. A muon overlapping with a pile-up jet can lead to a mis-tag, because the ID track from the muon represents a significant amount of p_T from the hard-scatter vertex and thus increases JVT. As a consequence of this fake tag, the pile-up jet p_T contributes to E_T^{miss} , and thus degrades both the E_T^{miss} response and resolution due to the stochastic nature of its contribution.

A jet that is reconstructed from a catastrophic energy loss of a muon tends to be tagged as a hard-scatter jet as well. This jet is reconstructed from topo-clusters in close proximity to the extrapolated trajectory of the ID track associated with the muon bend in the axial magnetic field. Inclusion of such a jet into E_T^{miss} reconstruction leads to double-counting of the transverse momentum associated with the muon energy loss, as the fully reconstructed muon p_T is already corrected for this effect.

To reject contributions from pile-up jets and jets reconstructed from muon energy loss, the following selection criteria are applied:

- $p_{T,\text{track}}^\mu / p_{T,\text{track}}^{\text{jet}} > 0.8$ – the transverse momentum of the ID track associated with the muon ($p_{T,\text{track}}^\mu$) represents a significant fraction of the transverse momentum $p_{T,\text{track}}^{\text{jet}}$, the sum of the transverse momenta of all ID tracks associated with the jet;
- $p_T^{\text{jet}} / p_{T,\text{track}}^\mu < 2$ – the overall transverse momentum p_T^{jet} of the jet is not too large compared to $p_{T,\text{track}}^\mu$;
- $N_{\text{track}}^{\text{PV}} < 5$ – the total number of tracks $N_{\text{track}}^{\text{PV}}$ associated with the jet and emerging from the hard-scatter vertex is small.

All jets with overlapping muons meeting these criteria are understood to be either from pile-up or a catastrophic muon energy loss and are rejected for E_T^{miss} reconstruction. The muons are retained for the E_T^{miss} reconstruction.

Another consideration for muon contributions to E_T^{miss} is FSR. Muons can radiate hard photons at small angles, which are typically not reconstructed as such because of the nearby muon ID track violating photon isolation requirements. They are also not reconstructed as electrons, due to the mismatch between the ID track momentum and the energy measured by the calorimeter. Most likely the calorimeter signal generated by the FSR photon is reconstructed as a jet, with the muon ID track associated. As the transverse momentum carried by the FSR photon is not recovered in muon reconstruction, jets representing this photon need to be included in the E_T^{miss} reconstruction. Such jets are characterised by the following

selections, which are highly indicative of a photon in the ATLAS calorimeter:

- $N_{\text{track}}^{\text{PV}} < 3$ – the jet has low charged-particle content, indicated by a very small number of tracks from the hard-scatter vertex;
- $f_{\text{EMC}} > 0.9$ – the jet energy E^{jet} is largely deposited in the electromagnetic calorimeter (EMC), as expected for photons and measured by the corresponding energy fraction $f_{\text{EMC}} = E_{\text{EMC}}^{\text{jet}} / E^{\text{jet}}$;
- $p_{T,\text{PS}}^{\text{jet}} > 2.5 \text{ GeV}$ – the transverse momentum contribution $p_{T,\text{PS}}^{\text{jet}}$ from presampler signals to p_T^{jet} indicates an early starting point for the shower;
- $w_{\text{jet}} < 0.1$ – the jet is narrow, with a width w_{jet} comparable to a dense electromagnetic shower; w_{jet} is reconstructed according to

$$w_{\text{jet}} = \frac{\sum_i \Delta R_i p_{T,i}}{\sum_i p_{T,i}},$$

where $\Delta R_i = \sqrt{(\Delta\eta_i)^2 + (\Delta\phi_i)^2}$ is the angular distance of topo-cluster i from the jet axis, and $p_{T,i}$ is the transverse momentum of this cluster;

- $p_{T,\text{track}}^{\text{jet}} / p_{T,\text{track}}^\mu > 0.8$ – the transverse momentum $p_{T,\text{track}}^{\text{jet}}$ carried by all tracks associated with the jet is close to $p_{T,\text{track}}^\mu$.

Jets are accepted for E_T^{miss} reconstruction when consistent with an FSR photon defined by the ensemble of these selection criteria, with their energy scale set to the EM scale, to improve the calibration.

3.4 E_T^{miss} soft term

The soft term introduced in Sect. 3.2 is exclusively reconstructed from ID tracks from the hard-scatter vertex, thus only using the p_T -flow from soft charged particles. It is an important contribution to E_T^{miss} for the improvement of both the E_T^{miss} scale and resolution, in particular in final states with a low hard-object multiplicity. In this case it is indicative of (hadronic) recoil, comprising the event components not otherwise represented by reconstructed and calibrated particles or jets.

The more inclusive reconstruction of the E_T^{miss} soft term including signals from soft neutral particles uses calorimeter topo-clusters. The reconstruction performance using the calorimeter-based $E_T^{\text{miss,soft,calo}}$ is inferior to the track-only-based $E_T^{\text{miss,soft}}$, mostly due to a larger residual dependence on pile-up. More details of the topo-cluster-based $E_T^{\text{miss,soft,calo}}$ reconstruction are discussed in Sect. 8.1.

3.4.1 Track and vertex selection

Hits in the ID are used to reconstruct tracks pointing to a particular collision vertex [18]. Both the tracks and vertices need to pass basic quality requirements to be accepted. Each event typically has a number $N_{PV} > 1$ of reconstructed primary vertices.

Tracks are required to have $p_T > 400$ MeV and $|\eta| < 2.5$, in addition to the reconstruction quality requirements given in Ref. [19]. Vertices are constructed from at least two tracks passing selections on the transverse (longitudinal) impact parameter $|d_0| < 1.5$ mm ($|z_0 \sin(\theta)| < 1.5$ mm) relative to the vertex candidate. These tracks must also pass requirements on the number of hits in the ID. The hard-scatter vertex is identified as described in Appendix A.

3.4.2 Track soft term

The track sample contributing to $E_T^{\text{miss,soft}}$ for each reconstructed event is collected from high-quality tracks emerging from the hard-scatter vertex but not associated with any electron, τ -lepton, muon, or jet contributing to E_T^{miss} reconstruction. The applied signal-overlap resolution removes

- ID tracks with $\Delta R(\text{track,electron/photon cluster}) < 0.05$;
- ID tracks with $\Delta R(\text{track, } \tau\text{-lepton}) < 0.2$;
- ID tracks associated with muons;
- ID tracks ghost-associated with fully or partially contributing jets.

ID tracks from the hard-scatter vertex that are associated with jets rejected by the overlap removal or are associated with jets that are likely from pile-up, as tagged by the JVT procedure discussed in Sect. 3.3.5, contribute to $E_T^{\text{miss,soft}}$.

Since only reconstructed tracks associated with the hard-scatter vertex are used, the track-based $E_T^{\text{miss,soft}}$ is largely insensitive to pile-up effects. It does not include contributions from any soft neutral particles, including those produced by the hard-scatter interaction.

4 Data and simulation samples

The determination of the E_T^{miss} reconstruction performance uses selected final states without ($E_T^{\text{miss,true}} = 0$) and with genuine missing transverse momentum from neutrinos ($E_T^{\text{miss,true}} = p_T^{\nu}$). Samples with $E_T^{\text{miss,true}} = 0$ are composed of leptonic Z boson decays ($Z \rightarrow ee$ and $Z \rightarrow \mu\mu$) collected by a trigger and event selection that do not depend on the particular pile-up conditions, since both the electron and muon triggers as well as the corresponding reconstructed kinematic variables are only negligibly affected by pile-up. Also using

lepton triggers, samples with neutrinos were collected from $W \rightarrow e\nu$ and $W \rightarrow \mu\nu$ decays. In addition, samples with neutrinos and higher hard-object multiplicity were collected from top-quark pair ($t\bar{t}$) production with at least either the t or the \bar{t} decaying semi-leptonically.

4.1 Data samples

The data sample used corresponds to a total integrated luminosity of 3.2 fb^{-1} , collected with a proton bunch-crossing interval of 25 ns. Only high-quality data with a well-functioning calorimeter, inner detector and muon spectrometer are analysed. The data-quality criteria are applied, which reduce the impact of instrumental noise and out-of-time calorimeter deposits from cosmic-ray and beam backgrounds.

4.2 Monte Carlo samples

The $Z \rightarrow \ell\ell$ and $W \rightarrow \ell\nu$ samples were generated using POWHEG-BOX [20] (version v1r2856) employing a matrix element calculation at next-to-leading order (NLO) in perturbative QCD. To generate the particle final state, the (parton-level) matrix element output was interfaced to PYTHIA8 [21],⁵ which generated the parton shower (PS) and the underlying event (UE) using the AZNLO tuned parameter set [22]. Parton distribution functions (PDFs) were taken from the CTEQ6L1 PDF set [23].

The $t\bar{t}$ -production sample was generated with a POWHEG NLO kernel (version v2r3026) interfaced to PYTHIA6 [24] (version 6.428) with the Perugia2012 set of tuned parameters [25] for the PS and UE generation. The CT10 NLO PDF set [26] was employed. The resummation of soft-gluon terms in the next-to-next-to-leading-logarithmic (NNLL) approximation with TOP++ 2.0 [27] was included.

Additional processes contributing to the $Z \rightarrow \ell\ell$ and $W \rightarrow \ell\nu$ final state samples are the production of dibosons, single top quarks, and multijets. Dibosons were generated using SHERPA [28–31] version v2.1.1 employing the CT10 PDF set. Single top quarks were generated using POWHEG version v1r2556 with the CT10 PDF set for the t -channel production and POWHEG version v1r2819 for the s -channel and the associated top quark (Wt) production, all interfaced to the PS and UE from the same PYTHIA6 configuration used for $t\bar{t}$ production. Multijet events were generated using PYTHIA8 with the NNPDF23LO PDF set [32] and the A14 set of tuned PS and UE parameters described in Ref. [33].

Minimum bias (MB) events were generated using PYTHIA8 with the MSTW2008LO PDF set [34] and the A2 tuned

⁵ Version 8.186 was used for all final states generated with PYTHIA8.

parameter set [35] for PS and UE. These MB events were used to model pile-up, as discussed in Sect. 4.3.

For the determination of the systematic uncertainties in E_T^{miss} reconstruction, an alternative inclusive sample of $Z \rightarrow \mu\mu$ events was generated using the MADGRAPH_AMC@NLO (version v2.2.2) matrix element generator [36] employing the CTEQ6L1 PDF set. Both PS and UE were generated using PYTHIA8 with the NNPDF23LO PDF set and the A14 set of tuned parameters.

The MC-generated events were processed with the GEANT4 software toolkit [37], which simulates the propagation of the generated stable particles⁶ through the ATLAS detector and their interactions with the detector material [38].

4.3 Pile-up

The calorimeter signals are affected by pile-up and the short bunch-crossing period at the LHC. In 2015, an average of about 13 pile-up collisions per bunch crossing was observed. The dominant contribution of the additional pp collisions to the detector signals of the recorded event arises from a diffuse emission of soft particles superimposed to the hard-scatter interaction final state (in-time pile-up). In addition, the LAr calorimeter signals are sensitive to signal remnants from up to 24 previous bunch crossings and one following bunch crossing (out-of-time pile-up), as discussed in Refs. [6, 39]. Both types of pile-up affect signals contributing to E_T^{miss} .

The in-time pile-up activity is measured by the number of reconstructed primary collision vertices N_{PV} . The out-of-time pile-up is proportional to the number of collisions per bunch crossing μ , measured as an average over time periods of up to two minutes by integrated signals from the luminosity detectors in ATLAS [40].

To model in-time pile-up in MC simulations, a number of generated pile-up collisions was drawn from a Poisson distribution around the value of μ recorded in data. The collisions were randomly collected from the MB sample discussed in Sect. 4.2. The particles emerging from them were overlaid onto the particle-level final state of the generated hard-scatter interaction and converted into detector signals before event reconstruction. The event reconstruction then proceeds as for data.

Similar to the LHC proton-beam structure, events in MC simulations are organised in bunch trains, where the structure in terms of bunch-crossing interval and gaps between trains is taken into account to model the effects of out-of-time pile-up. The fully reconstructed events in MC simulation samples are finally weighted such that the distribution of the number of overlaid collisions over the whole sample corresponds to the μ distribution observed in data.

⁶ In ATLAS stable particles are those with an expected laboratory lifetime τ corresponding to $c\tau > 10$ mm.

The effect of pile-up on the signal in the Tile calorimeter is reduced due to its location behind the electromagnetic calorimeter and its fast time response [41]. Reconstructed ID and MS tracks are largely unaffected by pile-up.

5 Event selection

5.1 $Z \rightarrow \mu\mu$ event selection

The $Z \rightarrow \mu\mu$ final state is ideal for the evaluation of E_T^{miss} reconstruction performance, since it can be selected with a high signal-to-background ratio and the Z kinematics can be measured with high precision, even in the presence of pile-up. Neutrinos are produced only through very rare heavy-flavour decays in the hadronic recoil. This channel can therefore be considered to have no genuine missing transverse momentum. Thus, the scale and resolution for the reconstructed E_T^{miss} are indicative of the reconstruction quality and reflect limitations introduced by both the detector and the ambiguity resolution procedure. The well-defined expectation value $E_T^{\text{miss,true}} = 0$ allows the reconstruction quality to be determined in both data and MC simulations. The reconstructed E_T^{miss} in this final state is also sensitive to the effectiveness of the muon-jet overlap resolution, which can be explored in this low-multiplicity environment in both data and MC simulations, with a well-defined E_T^{miss} .

Events must pass one of three high-level muon triggers with different p_T^μ thresholds and isolation requirements. The isolation is determined by the ratio of the scalar sum of p_T of reconstructed tracks other than the muon track itself, in a cone of size $\Delta R = 0.2$ around the muon track (p_T^{cone}), to p_T^μ . The individual triggers require (1) $p_T^\mu > 20$ GeV and $p_T^{\text{cone}}/p_T^\mu < 0.12$, or (2) $p_T^\mu > 24$ GeV and $p_T^{\text{cone}}/p_T^\mu < 0.06$, or (3) $p_T^\mu > 50$ GeV without isolation requirement.

The offline selection of $Z \rightarrow \mu\mu$ events requires exactly two muons, each selected as defined in Sect. 3.3.4, with the additional criteria that (1) the muons must have opposite charge, (2) $p_T^\mu > 25$ GeV, and (3) the reconstructed invariant mass $m_{\mu\mu}$ of the dimuon system is consistent with the mass m_Z of the Z boson, $|m_{\mu\mu} - m_Z| < 25$ GeV.

5.2 $W \rightarrow e\nu$ event selection

Events with $W \rightarrow e\nu$ or $W \rightarrow \mu\nu$ in the final state provide a well-defined topology with neutrinos produced in the hard-scatter interaction. In combination with $Z \rightarrow \mu\mu$, the effectiveness of signal ambiguity resolution and lepton energy reconstruction for both the electrons and muons can be observed. The $W \rightarrow e\nu$ events in particular provide a good metric with $E_T^{\text{miss,true}} = p_T^{\nu} > 0$ to evaluate and validate the scale, resolution and direction (azimuth) of the reconstructed E_T^{miss} , as the E_T^{miss} reconstruction is sensitive to the

electron–jet overlap resolution performance. This metric is only available in MC simulations where p_T^e is known. Candidate $W \rightarrow e\nu$ events are required to pass the high-level electron trigger with $p_T > 17$ GeV. Electron candidates are selected according to criteria described in Sect. 3.3.1. Only events containing exactly one electron are considered.

Further selections using E_T^{miss} and the reconstructed transverse mass m_T , given by

$$m_T = \sqrt{2p_T^e E_T^{\text{miss}}(1 - \cos \Delta\phi)},$$

are applied to reduce the multijet background with one jet emulating an isolated electron from the W boson. Here E_T^{miss} is calculated as presented in Sect. 3. The transverse momentum of the electron is denoted by p_T^e , and $\Delta\phi$ is the distance between ϕ^{miss} and the azimuth of the electron. Selected events are required to have $E_T^{\text{miss}} > 25$ GeV and $m_T > 50$ GeV.

5.3 $t\bar{t}$ event selection

Events with $t\bar{t}$ in the final state allow the evaluation of the E_T^{miss} performance in interactions with a large jet multiplicity. Electrons and muons used to define these samples are reconstructed as discussed in Sects. 3.3.1 and 3.3.4, respectively, and are required to have $p_T > 25$ GeV.

The final $t\bar{t}$ sample is selected by imposing additional requirements. Each event must have exactly one electron and no muons passing the selections described above. In addition, at least four jets reconstructed by the anti- k_r algorithm with $R = 0.4$ and selected following the description in Sect. 3.3.5 are required. At least one of the jets needs to be b -tagged using the tagger configuration for a 77% efficiency working point described in Ref. [42]. All jets are required to be at an angular distance of $\Delta R > 0.4$ from the electron.

6 Performance of E_T^{miss} reconstruction in data and Monte Carlo simulation

Unlike for fully reconstructed and calibrated particles and jets, and in the case of the precise reconstruction of charged particle kinematics provided by ID tracks, E_T^{miss} reconstruction yields a non-linear response, especially in regions of phase space where the observation bias discussed in Sect. 3.1 dominates the reconstructed E_T^{miss} . In addition, the E_T^{miss} resolution functions are characterised by a high level of complexity, due to the composite character of the observable. Objects with different p_T -resolutions contribute, and the E_T^{miss} composition can fluctuate significantly for events from the same final state. Due to the dependence of the E_T^{miss} response on the resolution, both performance characteristics change as a function of the total event activity and are

affected by pile-up. There is no universal way of mitigating these effects, due to the inability to validate in data a stable and universal calibration reference for E_T^{miss} .

The E_T^{miss} reconstruction performance is therefore assessed by comparing a set of reconstructed E_T^{miss} -related observables in data and MC simulations for the same final-state selection, with the same object and event selections applied. Systematic uncertainties in the E_T^{miss} response and resolution are derived from these comparisons and are used to quantify the level of understanding of the data from the physics models. The quality of the detector simulation is independently determined for all reconstructed jets, particles and ID tracks, and can thus be propagated to the overall E_T^{miss} uncertainty for any given event. Both the distributions of observables as well as their average behaviour with respect to relevant scales measuring the overall kinematic activity of the hard-scatter event or the pile-up activity are compared. To focus on distribution shapes rather than statistical differences in these comparisons, the overall distribution of a given observable obtained from MC simulations is normalised to the integral of the corresponding distribution in data.

As the reconstructed final state can be produced by different physics processes, the individual process contributions in MC simulations are scaled according to the cross section of the process. This approach is taken to both show the contribution of a given process to the overall distribution, and to identify possible inadequate modelling arising from any individual process, or a subset of processes, by its effect on the overall shape of the MC distribution.

Inclusive event samples considered for the E_T^{miss} performance evaluation are obtained by applying selections according to Sect. 5.1 for a final state without genuine E_T^{miss} ($Z \rightarrow \mu\mu$), and according to Sect. 5.2 for a final state with genuine E_T^{miss} ($W \rightarrow e\nu$). From these, specific exclusive samples are extracted by applying conditions on the number of jets reconstructed. In particular, *zero jet* ($N_{\text{jet}} = 0$) samples without any jet with $p_T > 20$ GeV (fully calibrated) and $|\eta| < 4.9$ are useful for exclusively studying the performance of the soft term. Samples with events selected on the basis of a non-zero number of reconstructed jets with $p_T > 20$ GeV are useful for evaluating the contribution of jets to E_T^{miss} . While the p_T response of jets is fully calibrated and provides a better measurement of the overall event p_T -flow, the p_T resolution for jets is affected by pile-up and can introduce a detrimental effect on E_T^{miss} reconstruction performance.

Missing transverse momentum and its related observables presented in Sect. 3.1 are reconstructed for the performance evaluations shown in the following sections using a standard reconstruction configuration. This configuration implements the signal ambiguity resolution in the E_T^{miss} reconstruction sequence discussed in Sect. 3.1. It employs the hard-object selections defined in Sects. 3.3.1–3.3.4, with jets selected according to the prescriptions given in Sect. 3.3.5.

The overlap resolution strategy for jets and muons described in Sect. 3.3.6 is applied. The soft term is formed from ID tracks according to Sect. 3.4.

6.1 E_T^{miss} modelling in Monte Carlo simulations

The quality of the MC modelling of E_x^{miss} , E_y^{miss} , E_T^{miss} and ΣE_T , reconstructed as given in Eqs. (1), (3) and (5), is evaluated for an inclusive sample of $Z \rightarrow \mu\mu$ events by comparing the distributions of these observables to data. The results are presented in Fig. 1. The data and MC simulations agree within 20% for the bulk of the E_T^{miss} distribution shown in Fig. 1a, with larger differences not accommodated by the total (systematic and statistical) uncertainties of the distributions for high E_T^{miss} . These differences suggest a mismodelling in $t\bar{t}$ events, the dominant background in the tail regime [43]. The ΣE_T distributions compared between data and MC simulations in Fig. 1b show discrepancies significantly larger than the overall uncertainties for $200 \text{ GeV} < \Sigma E_T < 1.2 \text{ TeV}$. These reflect the level of mismodelling of the final state mostly in terms of hard-object composition in MC simulations. The E_x^{miss} and E_y^{miss} spectra shown in Fig. 1c, d, respectively, show good agreement between data and MC simulations for the bulk of the distributions within $|E_{x(y)}^{\text{miss}}| < 100 \text{ GeV}$, with larger differences observed outside of this range still mostly within the uncertainties.

The distributions of individual contributions to E_T^{miss} from jets ($E_T^{\text{miss,jet}}$), muons ($E_T^{\text{miss,\mu}}$), and the soft term ($E_T^{\text{miss,soft}}$), as defined in Eq. (6), are compared between data and MC simulations for the same inclusive $Z \rightarrow \mu\mu$ sample in Fig. 2. Agreement between data and MC simulations for $E_T^{\text{miss,jet}}$ in Fig. 2a is of the order of $\pm 20\%$ and within the total uncertainties for $E_T^{\text{miss,jet}} \lesssim 120 \text{ GeV}$, but beyond those for higher $E_T^{\text{miss,jet}}$. A similar observation holds for $E_T^{\text{miss,\mu}}$ in Fig. 2b, where data and MC simulations agree within the uncertainties for low $E_T^{\text{miss,\mu}}$ but significantly beyond them for larger $E_T^{\text{miss,\mu}}$. Agreement between data and MC simulations is better for the soft term $E_T^{\text{miss,soft}}$, with differences up to 10% for $E_T^{\text{miss,soft}} \lesssim 30 \text{ GeV}$, as seen in Fig. 2c. Larger differences for larger $E_T^{\text{miss,soft}}$ are still found to be within the uncertainties.

The peak around $E_T^{\text{miss,jet}} = 20 \text{ GeV}$ indicates the onset of single-jet events at the threshold $p_T = 20 \text{ GeV}$ for jets contributing to $E_T^{\text{miss,jet}}$. Larger values of $E_T^{\text{miss,jet}}$ arise from events with one or more high- p_T jets balancing the p_T of the Z boson.

For the $W \rightarrow e\nu$ sample with genuine missing transverse momentum given by p_T^ν , both the total reconstructed E_T^{miss} and the soft term are compared between data and MC simulations in Fig. 3. The level of agreement between the E_T^{miss} distributions for data and MC simulations shown in Fig. 3a

for the inclusive event sample is at $\pm 20\%$, similar to that observed for the $Z \rightarrow \mu\mu$ sample in Fig. 1a, except that for this final state it is found to be within the total uncertainties of the measurement. The differences between the E_T^{miss} distributions observed with the exclusive $N_{\text{jet}} = 0$ sample shown in Fig. 3b are well below 20%, but show a trend to larger discrepancies for decreasing $E_T^{\text{miss}} \lesssim 40 \text{ GeV}$. This trend is due to the missing background contribution in MC simulations from multijet final states. The extraction of this contribution is very inefficient and only possible with large statistical uncertainties. Even very large MC samples of multijet final states provide very few events with only one jet that is accidentally reconstructed as an electron, and with the amount of E_T^{miss} required in the $W \rightarrow e\nu$ selection described in Sect. 5.2. The comparison of the $E_T^{\text{miss,soft}}$ distributions from data and MC simulations shown in Fig. 3c yields agreement well within the uncertainties, for $E_T^{\text{miss,soft}} \gtrsim 10 \text{ GeV}$. The rising deficiencies observed in the MC distribution for decreasing $E_T^{\text{miss,soft}} \lesssim 10 \text{ GeV}$ are expected to be related to the missing multijet contribution.

6.2 E_T^{miss} response and resolution

The response in the context of E_T^{miss} reconstruction is determined by the deviation of the observed E_T^{miss} from the expectation value for a given final state. This deviation sets the scale for the observed E_T^{miss} . If this deviation is independent of the genuine missing transverse momentum, or any other hard p_T indicative of the overall hard-scatter activity, the E_T^{miss} response is linear. In this case, a constant bias in the reconstructed E_T^{miss} is still possible due to detector inefficiencies and coverage (acceptance) limitations.

Final states balanced in transverse momentum are expected to show a non-linear E_T^{miss} response at low event activity, as the response in this case suffers from the observation bias in E_T^{miss} reconstruction discussed in Sect. 3.1. With increasing momentum transfers in the hard-scatter interaction, the E_T^{miss} response becomes increasingly dominated by a well-measured hadronic recoil and thus more linear. In the case of final states with genuine missing transverse momentum, the E_T^{miss} response is only linear once $E_T^{\text{miss,true}}$ exceeds the observation bias. These features are discussed in Sect. 6.2.1 and explored in Sect. 6.2.2.

Contributions to the fluctuations in the E_T^{miss} measurement arise from (1) the limitations in the detector acceptance not allowing the reconstruction of the complete transverse momentum flow from the hard interaction, (2) the irreducible intrinsic signal fluctuations in the detector response, and from (3) the additional response fluctuations due to pile-up. In particular (1) introduces fluctuations driven by the large variations of the particle composition of the final state with respect to their types, momenta and directions. The limited detector

ing evaluations are the overall event activity represented by ΣE_T , and the pile-up activity measured by N_{PV} . The measurement of the E_T^{miss} resolution is discussed in Sect. 6.2.3 and results are presented in Sect. 6.2.4.

6.2.1 E_T^{miss} scale determination

In events with $Z \rightarrow \mu\mu$ decays, the transverse momentum of the Z boson (p_T^Z) is an indicator of the hardness of the interaction. It provides a useful scale for the evaluation of the E_T^{miss} response for this final state without genuine missing transverse momentum. The direction of the corresponding Z boson transverse momentum vector \mathbf{p}_T^Z defines an axis \mathbf{A}_Z in the transverse plane of the collision, which is reconstructed from the \mathbf{p}_T of the decay products by

$$\mathbf{A}_Z = \frac{\mathbf{p}_T^{\mu^+} + \mathbf{p}_T^{\mu^-}}{|\mathbf{p}_T^{\mu^+} + \mathbf{p}_T^{\mu^-}|} = \frac{\mathbf{p}_T^Z}{p_T^Z}. \tag{9}$$

The magnitude of the component of $\mathbf{E}_T^{\text{miss}}$ parallel to \mathbf{A}_Z is

$$\mathcal{P}_{\parallel}^Z = \mathbf{E}_T^{\text{miss}} \cdot \mathbf{A}_Z. \tag{10}$$

This projection is sensitive to any limitation in E_T^{miss} reconstruction, in particular with respect to the contribution from the hadronic recoil against \mathbf{p}_T^Z , both in terms of response and resolution. Because it can be determined both for data and MC simulations, it provides an important tool for the validation of the E_T^{miss} response and the associated systematic uncertainties.

The expectation value for a balanced interaction producing a Z boson against a hadronic recoil is $E[\mathcal{P}_{\parallel}^Z] = 0$. Any observed deviation from this value represents a bias in the E_T^{miss} reconstruction. For $\mathcal{P}_{\parallel}^Z < 0$, the reconstructed hadronic activity recoiling against \mathbf{p}_T^Z is too small, while for $\mathcal{P}_{\parallel}^Z > 0$ too much hadronic recoil is reconstructed. The evolution of $\mathcal{P}_{\parallel}^Z$ as a function of the hardness of the Z boson production can be measured by evaluating the mean $\langle \mathcal{P}_{\parallel}^Z \rangle$ in bins of the hard-scatter scale $p_T^{\text{hard}} = p_T^Z$.

In addition to measuring the E_T^{miss} response in data and MC simulation without genuine E_T^{miss} , its linearity can be determined using samples of final states with genuine E_T^{miss} in MC simulations. This is done by evaluating the relative deviation Δ_T^{lin} of the reconstructed E_T^{miss} from the expected $E_T^{\text{miss,true}} > 0$ as a function of $E_T^{\text{miss,true}}$,

$$\Delta_T^{\text{lin}}(E_T^{\text{miss,true}}) = \frac{E_T^{\text{miss}} - E_T^{\text{miss,true}}}{E_T^{\text{miss,true}}}. \tag{11}$$

6.2.2 Measuring the E_T^{miss} response

Figure 4 shows $\langle \mathcal{P}_{\parallel}^Z \rangle$ as a function of p_T^Z for the $N_{\text{jet}} = 0$ and the inclusive $Z \rightarrow \mu\mu$ sample, respectively. MC simulations compare well with the data for $N_{\text{jet}} = 0$, but show larger deviations up to 30% for the inclusive selection. Nevertheless, these differences are still found to be within the total uncertainty of the measurement.

The steep decrease of $\langle \mathcal{P}_{\parallel}^Z \rangle$ with increasing p_T^Z in the $N_{\text{jet}} = 0$ sample seen in Fig. 4a reflects the inherent underestimation of the soft term, as in this case the hadronic recoil is exclusively represented by ID tracks with $p_T > 400$ MeV within $|\eta| < 2.5$. It thus does not contain any signal from (1) neutral particles, (2) charged particles produced with $|\eta| > 2.5$, and (3) charged particles produced within $|\eta| < 2.5$ but with p_T below threshold, rejected by the track quality requirements, or not represented by a track at all due to insufficient signals in the ID (e.g., lack of hits for track fitting).

In the case of the inclusive sample shown in Fig. 4b, the E_T^{miss} response is recovered better as p_T^Z increases, since an increasing number of events enter the sample with a reconstructed recoil containing fully calibrated jets. These provide a more complete representation of the hadronic transverse momentum flow. The residual offsets in $\langle \mathcal{P}_{\parallel}^Z \rangle$ of about 8 GeV in data and 6 GeV in MC simulations observed for $p_T^Z \gtrsim 40$ GeV in Fig. 4b agree within the uncertainties of this measurement.

The persistent bias in $\langle \mathcal{P}_{\parallel}^Z \rangle$ is further explored in Fig. 5, which compares variations of $\langle \mathcal{P}_{\parallel}^Z \rangle$ respectively using the full $\mathbf{E}_T^{\text{miss}}$, the soft-term contribution $\mathbf{E}_T^{\text{miss,soft}}$ only, the hard-term contribution $\mathbf{E}_T^{\text{miss}} - \mathbf{E}_T^{\text{miss,soft}}$, and the true soft term $\mathbf{E}_T^{\text{miss,true soft}}$ only, as a function of p_T^Z , for the $Z \rightarrow \mu\mu$ sample from MC simulations. In particular the difference between the projections using $\mathbf{E}_T^{\text{miss,true soft}}$ and $\mathbf{E}_T^{\text{miss,soft}}$ indicates the lack of reconstructed hadronic response, when $\mathbf{E}_T^{\text{miss,soft}} = \mathbf{E}_T^{\text{miss,true soft}}$ is expected for a fully measured recoil. The parallel projection using only the soft terms is larger than zero for all p_T^Z due to the missing Z -boson contribution to $\mathbf{E}_T^{\text{miss}}$ given by $-\mathbf{p}_T^Z$.

The deviation from linearity in E_T^{miss} reconstruction, measured by Δ_T^{lin} given in Eq. (11), is shown as a function of $E_T^{\text{miss,true}}$ for MC simulations of $W \rightarrow e\nu$, $W \rightarrow \mu\nu$ and $t\bar{t}$ production in Fig. 6. The observed $\Delta_T^{\text{lin}} > 0$ at low $E_T^{\text{miss,true}}$ indicates an overestimation of $E_T^{\text{miss,true}}$ by the reconstructed E_T^{miss} due to the observation biases arising from the finite E_T^{miss} resolution, as discussed in Sect. 3.1. This bias overcompensates the lack of reconstructed p_T -flow from the incompletely measured hadronic recoil in $W \rightarrow e\nu$ and $W \rightarrow \mu\nu$ events for $E_T^{\text{miss,true}} \lesssim 40$ GeV with an increasing non-linearity observed with decreasing $E_T^{\text{miss,true}}$. For $E_T^{\text{miss,true}} \gtrsim 70$ GeV the E_T^{miss} response is directly pro-

Fig. 4 The average projection of E_T^{miss} onto the direction A_Z of the Z boson's transverse momentum vector p_T^Z , as given in Eq. (10), is shown as a function of $p_T^Z = |\mathbf{p}_T^Z|$ in $Z \rightarrow \mu\mu$ events from **a** the $N_{\text{jet}} = 0$ sample and from **b** the inclusive sample. In both cases data are compared to MC simulations. The ratio of the averages from data and MC simula-

tions are shown below the plots. The shaded areas indicate the overall statistical uncertainty combined with systematic uncertainties comprising contributions from the muon and soft-term systematic uncertainties in **a**, and including the additional jet systematic uncertainties in **b**, for MC simulations

Fig. 5 The average projection of E_T^{miss} onto the direction A_Z of the Z boson's transverse momentum vector p_T^Z , as given in Eq. (10), is shown as a function of $p_T^Z = |\mathbf{p}_T^Z|$ in $Z \rightarrow \mu\mu$ events from the inclusive MC sample. The average projection of the soft term and the true soft term are also shown, to demonstrate the source of the deviation from zero

portional to $E_T^{\text{miss,true}}$, with the reconstructed recoil being approximately 2% too small. The $W \rightarrow e\nu$ and $W \rightarrow \mu\nu$ final states show very similar $\Delta_T^{\text{lin}}(E_T^{\text{miss,true}})$, thus indicating the universality of the recoil reconstruction and the independence on the lepton flavour of the reconstructed E_T^{miss} in a low-multiplicity final state with $E_T^{\text{miss,true}} > 0$.

Fig. 6 The deviation of the E_T^{miss} response from linearity, measured as a function of the expected $E_T^{\text{miss,true}}$ by Δ_T^{lin} in Eq. (11), in $W \rightarrow e\nu$, $W \rightarrow \mu\nu$, and $t\bar{t}$ final states in MC simulations. The lower plot shows a zoomed-in view on the Δ_T^{lin} dependence on $E_T^{\text{miss,true}}$ with a highly suppressed ordinate

In $t\bar{t}$ final-state reconstruction, resolution effects tend to dominate Δ_T^{lin} at $E_T^{\text{miss,true}} \lesssim 120$ GeV. Compared to the $W \rightarrow e\nu$ and $W \rightarrow \mu\nu$ final states, a signifi-

cantly poorer E_T^{miss} resolution is observed in this kinematic region, due to the presence of at least four jets with relatively low p_T and high sensitivity to pile-up-induced fluctuations in each event of the $t\bar{t}$ sample. For $E_T^{\text{miss,true}} > 120 \text{ GeV}$, $\Delta_T^{\text{lin}}(E_T^{\text{miss,true}}) \approx 2\%$ indicates a proportional E_T^{miss} response with a systematic shift similar to the one observed in inclusive W -boson production.

6.2.3 Determination of the E_T^{miss} resolution

The E_T^{miss} resolution is determined by the width of the combined distribution of the differences between the measured $E_{x(y)}^{\text{miss}}$ and the components of the true missing transverse momentum vector $\mathbf{E}_T^{\text{miss,true}} = (E_x^{\text{miss,true}}, E_y^{\text{miss,true}})$. The width is measured in terms of the RMS, with

$$\text{RMS}_{x(y)}^{\text{miss}} = \begin{cases} \text{RMS}(E_{x(y)}^{\text{miss}} - E_{x(y)}^{\text{miss,true}}) & W \rightarrow e\nu \text{ or } t\bar{t} \text{ sample } (E_T^{\text{miss,true}} > 0) \\ \text{RMS}(E_{x(y)}^{\text{miss,true}}) & Z \rightarrow \mu\mu \text{ sample } (E_T^{\text{miss,true}} = 0) \end{cases} \quad (12)$$

This metric does not capture all of the effects driving the fluctuations in E_T^{miss} reconstruction, such as biases between individual E_T^{miss} terms or the behaviour of outliers, but it is an appropriate general measure of how well E_T^{miss} represents $E_T^{\text{miss,true}}$.

Using the $Z \rightarrow \mu\mu$ sample allows direct comparisons of $\text{RMS}_{x(y)}^{\text{miss}}$ between data and MC simulations, as $E_T^{\text{miss,true}} = 0$ in this case. The resolution in final states with genuine E_T^{miss} is determined with MC simulations alone. For $W \rightarrow e\nu$ and $t\bar{t}$ final states, $E_{x(y)}^{\text{miss,true}} = p_{x(y)}^{\nu}$ is used.

6.2.4 E_T^{miss} resolution measurements

The E_T^{miss} resolution measured by $\text{RMS}_{x(y)}^{\text{miss}}$ is evaluated as a function of the event activity measured by ΣE_T given in Eq. (7). For the inclusive $Z \rightarrow \mu\mu$ sample, Fig. 7a shows $\text{RMS}_{x(y)}^{\text{miss}}$ quickly rising from less than 5 GeV to about 10 GeV with increasing ΣE_T within $50 \text{ GeV} \leq \Sigma E_T < 70 \text{ GeV}$.⁷ This is due to the fact that in this range the two muons are the dominant hard objects contributing, with a p_T resolution proportional to $(p_T^{\mu})^2$. A convolution of the muon resolution with a small contribution from $E_T^{\text{miss,soft}}$ is possible for $\Sigma E_T > 50 \text{ GeV}$. This component is on average about 60% of p_T^Z , and subject to the stochastic fluctuations further discussed below.

The increase of $Z \rightarrow \mu\mu + 1$ jet topologies in the $Z \rightarrow \mu\mu$ sample leads to an additional source of fluctuations affecting

⁷ This lower boundary of this range is given by the muon selection with $p_T^{\mu} > 25 \text{ GeV}$, as described in Sect. 5.1, assuming no other hard-scatter vertex tracks, i.e. $E_T^{\text{miss,soft}} = 0$. The upper boundary indicates the lower limit of ΣE_T to accommodate at least one jet with $p_T^{\text{jet}} > 20 \text{ GeV}$ in addition the two muons (for the jet selection see Sect. 3.3.5).

$\text{RMS}_{x(y)}^{\text{miss}}(\Sigma E_T)$ for $70 \text{ GeV} < \Sigma E_T \lesssim 180 \text{ GeV}$. In general the $Z \rightarrow \mu\mu$ sample collected for this study covers $p_T^Z \lesssim 140 \text{ GeV}$ with relevant statistics. At this limit it is expected that the hadronic recoil contains two reconstructed jets, with the onset of this contribution at ΣE_T of about 180 GeV. The corresponding change of the dominant final state composition for $\Sigma E_T > 180 \text{ GeV}$ leads to a change of shape of $\text{RMS}_{x(y)}^{\text{miss}}(\Sigma E_T)$, as the transverse momentum of the individual jets rises and the number of contributing jets slowly increases. The expected $\text{RMS}_{x(y)}^{\text{miss}}(\Sigma E_T) \propto \sqrt{\Sigma E_T}$ scaling driven by the jet- p_T resolution [44] therefore dominates $\text{RMS}_{x(y)}^{\text{miss}}$ at these higher ΣE_T . The MC predictions for $\text{RMS}_{x(y)}^{\text{miss}}(\Sigma E_T)$ agree with the data within a few percent and well within the total uncertainties of this measurement. A tendency for slightly poorer resolution in MC simulations is observed, in particular for $\Sigma E_T > 200 \text{ GeV}$.

Any contribution from pile-up to $\text{RMS}_{x(y)}^{\text{miss}}$ is expected to be associated with the jets. While dedicated corrections applied to the jets largely suppress pile-up contributions in the jet response, residual irreducible fluctuations introduced into the calorimeter signals by pile-up lead to a degradation of the jet energy resolution and thus poorer resolution in the jet- p_T measurement. The dependence of $\text{RMS}_{x(y)}^{\text{miss}}$ on the pile-up activity measured by N_{PV} is shown in Fig. 7b. Data show a less steep slope of $\text{RMS}_{x(y)}^{\text{miss}}(N_{\text{PV}})$ than MC simulations, but with about 10% worse resolution in the low pile-up region of $N_{\text{PV}} \lesssim 5$. The resolution in data is better than in MC simulations by about 10% for the region of higher pile-up activity at $N_{\text{PV}} \approx 20$.

The differences between data and MC simulations seen in $\text{RMS}_{x(y)}^{\text{miss}}(\Sigma E_T)$ for the inclusive $Z \rightarrow \mu\mu$ sample can be further analysed by splitting the sample according to the value of N_{jet} . Figure 8a shows the dependence of $\text{RMS}_{x(y)}^{\text{miss}}$ on ΣE_T for $Z \rightarrow \mu\mu$ events with $N_{\text{jet}} = 0$. The dominant source of fluctuations other than the muon- p_T resolution is in this case introduced by the incomplete reconstruction of the hadronic recoil. These fluctuations increase with increasing p_T^Z , which in turn means higher overall event activity measured by ΣE_T . For this sample $\text{RMS}_{x(y)}^{\text{miss}}$ in data compares well to MC simulations, at a level of a few percent, without any observed dependence on ΣE_T .

The exclusive $N_{\text{jet}} \geq 1$ samples extracted from $Z \rightarrow \mu\mu$ data and MC simulations show the expected $\text{RMS}_{x(y)}^{\text{miss}} \propto \sqrt{\Sigma E_T}$ scaling in Fig. 8b. The resolution in data is well represented by MC simulations, at the level of a few percent. The slightly better resolution observed in data with increasing ΣE_T follows the trend observed in Fig. 7a. The similar trends are expected as this kinematic region is largely affected by the jet contribution.

The dependence of $\text{RMS}_{x(y)}^{\text{miss}}$ on N_{PV} shown in Fig. 8c indicates that the E_T^{miss} resolution is basically independent of pile-up, for the $N_{\text{jet}} = 0$ sample. This is expected from the

Fig. 7 The RMS width of the $E_{x(y)}^{\text{miss}}$ distributions **a** in bins of ΣE_T and **b** in bins of the number of primary vertices in an inclusive sample of $Z \rightarrow \mu\mu$ events. Predictions from MC simulations are overlaid on

exclusive E_T^{miss} composition comprising the (track-based) $E_T^{\text{miss},\mu}$ and $E_T^{\text{miss},\text{soft}}$ terms only. Data and MC simulations compare well within a few percent, and without any observable dependence on N_{PV} . Figure 8d shows the N_{PV} dependence of $\text{RMS}_{x(y)}^{\text{miss}}$ for the $N_{\text{jet}} \geq 1$ sample. Comparing this result to Fig. 7b confirms that all pile-up dependence of the E_T^{miss} resolution is arising from the jet term. Both trend and magnitude of the data-to-MC comparison follow the observation from the inclusive analysis.

6.2.5 E_T^{miss} resolution in final states with neutrinos

The E_T^{miss} resolution for final states with $E_T^{\text{miss,true}} > 0$ is measured by $\text{RMS}_{x(y)}^{\text{miss}}$ according to Eq. (12) and evaluated using dedicated inclusive $W \rightarrow e\nu$ and $W \rightarrow \mu\nu$ samples from MC simulations, and the inclusive $t\bar{t}$ MC sample defined in Sect. 5.3. For these samples, $\text{RMS}_{x(y)}^{\text{miss}}$ can be determined as a function of $E_T^{\text{miss,true}} = p_T^\nu$. The dedicated $W \rightarrow e\nu$ and $W \rightarrow \mu\nu$ samples are obtained with an event selection based on the description in Sect. 5.2, but omitting both the E_T^{miss} -based and the m_T -based selections.

Figure 9 shows $\text{RMS}_{x(y)}^{\text{miss}}$ evaluated as a function of $E_T^{\text{miss,true}}$ for these samples. The universality of the response to the hadronic recoil observed in Fig. 6, together with the different but subdominant contributions from the p_T resolutions of the electrons and muons, yield a very similar E_T^{miss} resolution for $W \rightarrow e\nu$ and $W \rightarrow \mu\nu$ final states. Generally, poorer

the data points, and the ratios are shown below the respective plot. The shaded bands indicate the combined statistical and systematic uncertainties of the resolution measurements

resolution is observed in $t\bar{t}$ final states. The deviation from the expected $\text{RMS}_{x(y)}^{\text{miss}} \propto \sqrt{(E_T^{\text{miss,true}})}$ scaling behaviour for $W \rightarrow \ell\nu$ at lower $E_T^{\text{miss,true}}$ reflects the kinematic features of the W boson and its decay. Events with low p_T^W , and therefore small hadronic recoil, lie predominantly in the region $25 \text{ GeV} \lesssim p_T^\nu \lesssim 50 \text{ GeV}$. Since the hadronic recoil is generally the poorly measured component of an event and the reconstructed E_T^{miss} is dominated by the lepton p_T in this region, the E_T^{miss} resolution tends to be better here than for events with larger hadronic recoil populating $p_T^\nu \lesssim 25 \text{ GeV}$ and $p_T^\nu \gtrsim 50 \text{ GeV}$.

6.3 E_T^{miss} tails

Large reconstructed E_T^{miss} is an indicator for the production of (potentially new) undetectable particles, but can also be generated by detector problems and/or poor reconstruction of the objects used for its reconstruction. Enhanced tails in the distribution of the E_T^{miss} components for final states with well-known expectation values for E_T^{miss} are indicative of such inefficiencies.

Non-Gaussian shapes in the distribution arise from a combination of object selection inefficiencies and potentially non-Gaussian resolutions of the E_T^{miss} constituents. Even for a well-defined final state, event-by-event fluctuations in terms of which particles, jets, and soft tracks enter the E_T^{miss} reconstruction, and with which p_T , lead to deviations from a normally distributed $(E_x^{\text{miss}}, E_y^{\text{miss}})$ response.

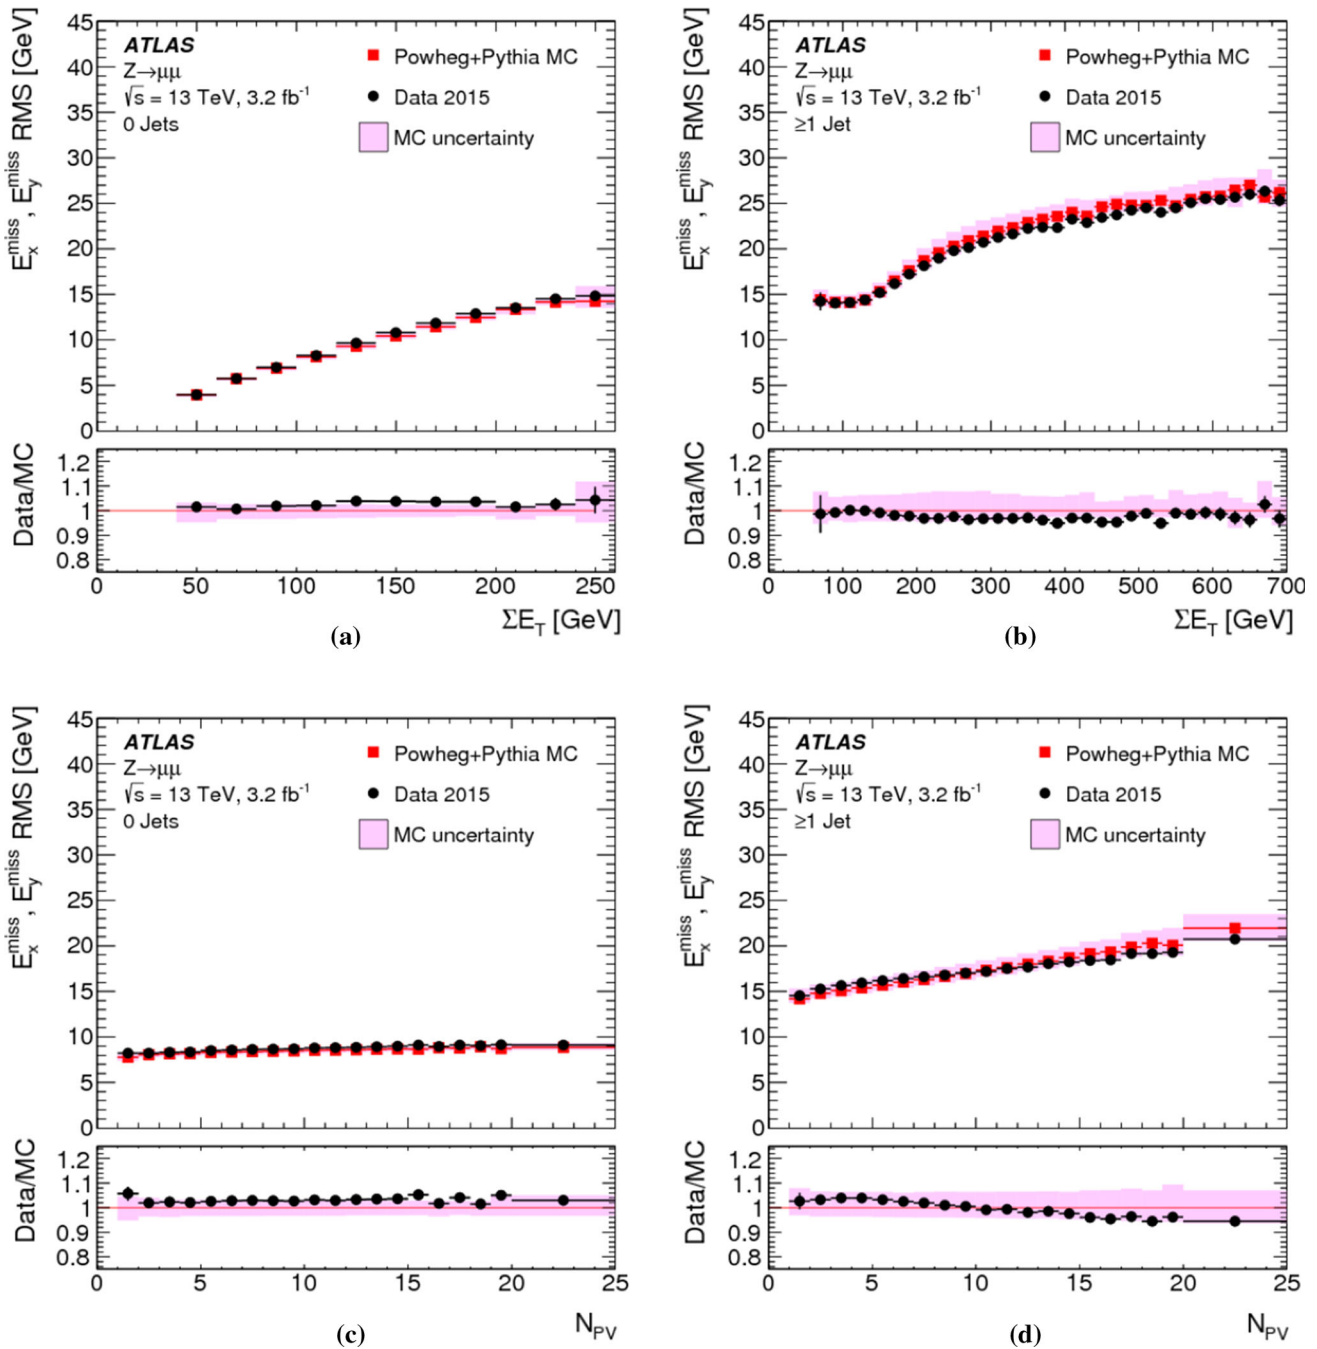

Fig. 8 The E_T^{miss} resolution $\text{RMS}_{x(y)}^{\text{miss}}$ determined for **a** an exclusive $Z \rightarrow \mu\mu$ sample without jets with $p_T > 20 \text{ GeV}$ ($N_{\text{jet}} = 0$) and for **b** an exclusive sample with at least one jet above this threshold ($N_{\text{jet}} \geq 1$), as a function of ΣE_T in data and MC simulations. The dependence of

$\text{RMS}_{x(y)}^{\text{miss}}$ on the pile-up activity, as measured by N_{PV} , for these two samples is shown in **c** and **d**, respectively. The shaded bands indicate the combined statistical and systematic uncertainties associated with the measurement

Figure 10 shows the combined $(E_x^{\text{miss}}, E_y^{\text{miss}})$ distribution for the inclusive $Z \rightarrow \mu\mu$ sample from MC simulations. To illustrate its symmetric nature and its deviation from a normal distribution in particular with respect to the tails, Gaussian functions are fitted to two limited ranges around the centre of the distribution, $\pm 1 \times \text{RMS}$ and $\pm 2 \times \text{RMS}$.

The differences between these functions and the data distribution (lower panel of Fig. 10) indicate a more peaked shape around the most probable value for $E_{x(y)}^{\text{miss}}$ with near exponential slopes. The result of this comparison supports the choice of $\text{RMS}_{x(y)}^{\text{miss}}$ defined in Eq. (12) in Sect. 6.2.3 for the determination of the E_T^{miss} resolution, rather than using any of

Fig. 9 The E_T^{miss} resolution measured by $\text{RMS}_{x(y)}^{\text{miss}}$ as a function of the true missing transverse momentum $E_T^{\text{miss,true}}$ for the $W \rightarrow e\nu$, $W \rightarrow \mu\nu$, and $t\bar{t}$ samples from MC simulations

Fig. 10 The combined distribution of E_x^{miss} and E_y^{miss} for an inclusive $Z \rightarrow \mu\mu$ from simulation. Gaussian fits limited to the $\pm 1 \times \text{RMS}$ and $\pm 2 \times \text{RMS}$ ranges around the centre of the distribution are shown, together with the respective differences between the fitted functions and the actual distribution

the widths measured by fitting Gauss functions in selected ranges of the distribution.

The tails in this shape are reflected in the distribution of E_T^{miss} itself and can be estimated by measuring the fraction of events with $E_T^{\text{miss}} > E_T^{\text{miss,threshold}}$,

$$f_{\text{tail}} = \frac{1}{\mathcal{H}} \int_{E_T^{\text{miss,threshold}}}^{\infty} h(E_T^{\text{miss}}) dE_T^{\text{miss}},$$

$$\text{with } \mathcal{H} = \int_0^{\infty} h(E_T^{\text{miss}}) dE_T^{\text{miss}}. \tag{13}$$

Here $h(E_T^{\text{miss}})$ is the E_T^{miss} distribution for a given event sample, and $E_T^{\text{miss,threshold}}$ is a threshold set to estimate tails. Any decrease of f_{tail} at a fixed integral \mathcal{H} indicates an improvement of the E_T^{miss} resolution, and is more sensitive to particular improvements than e.g. $\text{RMS}_{x(y)}^{\text{miss}}$. For example, improving the $E_T^{\text{miss,soft}}$ reconstruction by rejecting ID tracks from the hard-scatter vertex with poor reconstruction quality yields a significantly smaller f_{tail} for the same event sample.

The tails in the E_T^{miss} distributions for the final states considered for this study are quantified by the fraction of events above a certain E_T^{miss} threshold using MC simulations. Figure 11a shows that the $Z \rightarrow \ell\ell$ events ($\ell = e$ or $\ell = \mu$) with $E_T^{\text{miss,true}} = 0$ have significantly reduced tails when compared to $W \rightarrow \ell\nu$ and $t\bar{t}$ with this metric, and that the tails do not depend on the lepton flavour. A modification of this metric, taking into account $E_T^{\text{miss,true}}$ such that the fraction of events with $|E_T^{\text{miss}} - E_T^{\text{miss,true}}|$ above a given threshold is determined, shows the universality of the hadronic recoil in $Z \rightarrow \ell\ell$ and $W \rightarrow \ell\nu$, as can be seen in Fig. 11b.

Another finding of this study is that the tail in the $|E_T^{\text{miss}} - E_T^{\text{miss,true}}|$ distribution for the higher ΣE_T^{jet} $t\bar{t}$ sample is considerably larger than for the low- ΣE_T^{jet} samples with $Z \rightarrow \ell\ell$ or $W \rightarrow \ell\nu$ final states. As can be seen in Fig. 11c, the tails are much more consistent between $Z \rightarrow \mu\mu$ and $t\bar{t}$ samples when the distribution for the $Z \rightarrow \mu\mu$ sample is reweighted such that it follows the same ΣE_T^{jet} distribution as the $t\bar{t}$ sample. The enhanced tails are thus likely introduced by the jet response and multiplicity, which has a residual sensitivity to pile-up.

7 Systematic uncertainties

The systematic uncertainties associated with the measurement of E_T^{miss} are provided for the response (E_T^{miss} scale) as well as for the resolution. They depend on the composition of the hard terms and on the magnitude of the corresponding soft term. As the hard-term composition is generally defined by optimisations implemented in the context of a given analysis, the contributions of the E_T^{miss} terms need to be extracted from the scale and resolution uncertainties for the individual contributing objects comprising electrons, photons, muons, τ -leptons, and jets. In the corresponding propagations, cor-

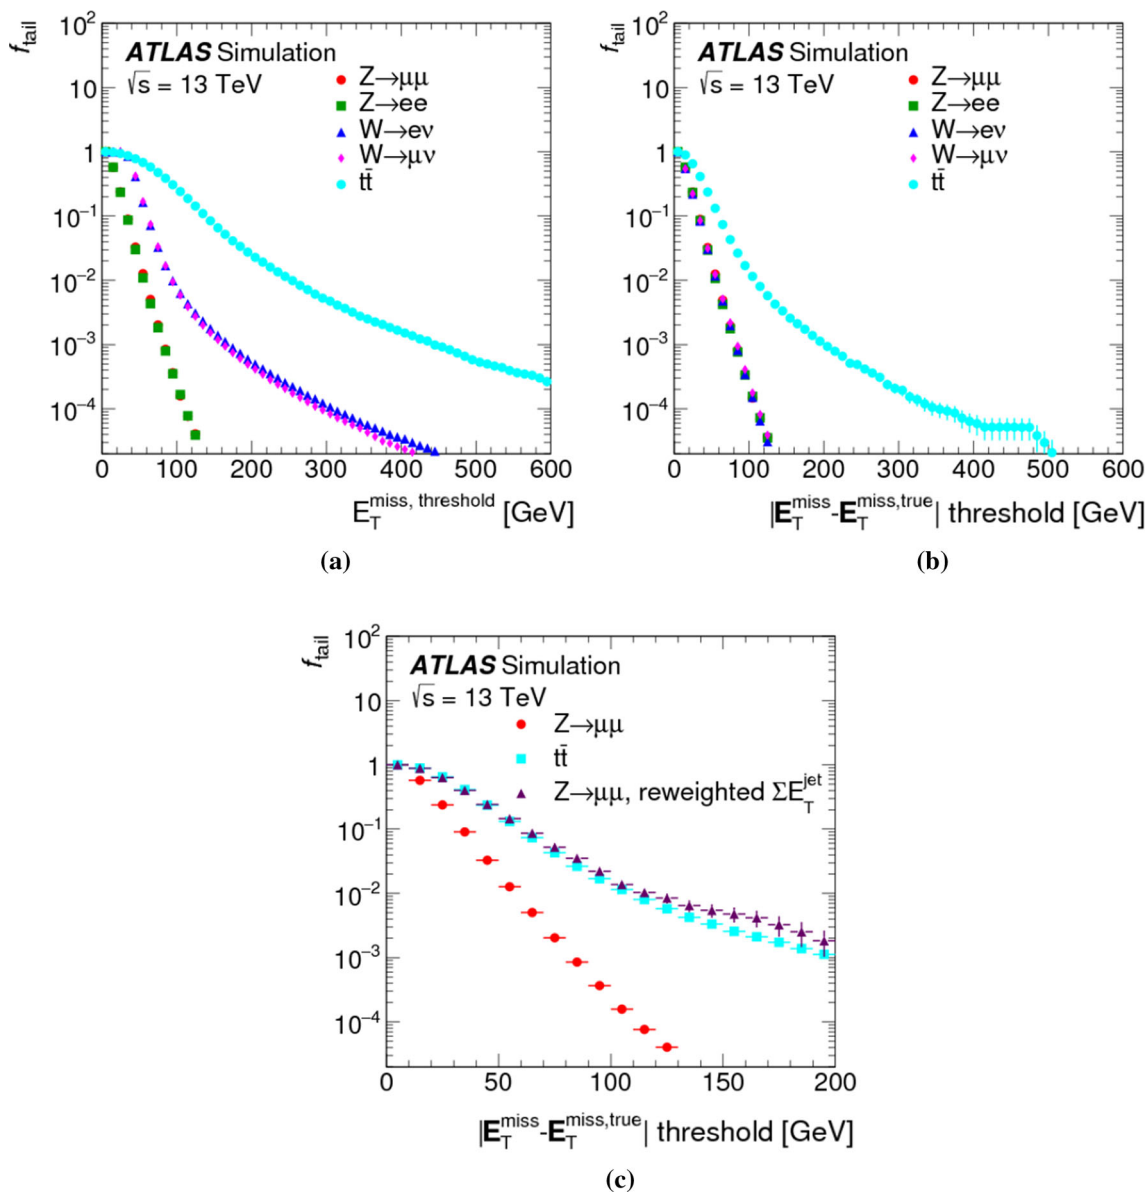

Fig. 11 In **a** the integral tail fraction f_{tail} given in Eq. (13) is shown as a function of the integration threshold $E_T^{\text{miss,threshold}}$, for MC simulations of $Z \rightarrow \ell\ell$, $W \rightarrow \ell\nu$, and $t\bar{t}$ final states. The tail fraction in terms of a threshold applied to $|E_T^{\text{miss}} - E_T^{\text{miss,true}}|$, the distance between the reconstructed (E_T^{miss}) and the expected ($E_T^{\text{miss,true}}$) vectors, is shown in

b for all considered final states. The same fraction is shown in **c** for the E_T^{miss} distributions for $Z \rightarrow \mu\mu$ before and after a reweighting following the ΣE_T distribution for $t\bar{t}$ is applied, together with f_{tail} from the $t\bar{t}$ final state

relations between systematic uncertainties for the same type of object are typically taken into account. However, it is assumed that systematic uncertainties of the different object types entering E_T^{miss} reconstruction are uncorrelated. The determination of the E_T^{miss} scale and resolution uncertainties arising from the soft term $E_T^{\text{miss,soft}}$ is described in this section.

7.1 Methodology

The extraction of the systematic uncertainties for the reconstructed E_T^{miss} is based on data-to-MC comparisons of spectra of observables measuring the contribution of $E_T^{\text{miss,soft}}$ to the overall E_T^{miss} .

7.1.1 Observables

The vector sum of the transverse momentum vectors of all particles and jets emerging from a hard-scatter interaction (\mathbf{p}_T^{HS}) is given by

$$\mathbf{p}_T^{\text{HS}} = \underbrace{\sum \mathbf{p}_T^e + \sum \mathbf{p}_T^\gamma + \sum \mathbf{p}_T^\tau + \sum \mathbf{p}_T^\mu + \sum \mathbf{p}_T^{\text{jet}}}_{\mathbf{p}_T^{\text{obs}} \text{ (observable)}} + \underbrace{\sum \mathbf{p}_T^{\nu}}_{\mathbf{p}_T^{\text{inv}} \text{ (not observable)}}$$

Here \mathbf{p}_T^{ν} generally represents the transverse momenta of non-observable particles, which are summed up to form $\mathbf{p}_T^{\text{inv}}$. All other transverse momenta are carried by particles that are observable in principle, and sum up to $\mathbf{p}_T^{\text{obs}}$. Momentum conservation dictates $p_T^{\text{HS}} = |\mathbf{p}_T^{\text{HS}}| = 0$.

Due to detector acceptance limitations and inefficiencies in hard-object reconstruction and calibration, and all other effects discussed in Sect. 3, only a proxy ($\mathbf{p}_T^{\text{hard}}$) for the observable-particle contribution $\mathbf{p}_T^{\text{obs}}$ can be measured. The reconstructed hard final-state objects entering E_T^{miss} as described in Sect. 3.2 are used to measure $\mathbf{p}_T^{\text{hard}}$ as

$$\mathbf{p}_T^{\text{hard}} = \sum_{\text{contributing electrons}} \mathbf{p}_T^e + \sum_{\text{contributing photons}} \mathbf{p}_T^\gamma + \sum_{\text{contributing } \tau\text{-leptons}} \mathbf{p}_T^{\tau\text{had}} + \sum_{\text{contributing muons}} \mathbf{p}_T^\mu + \sum_{\text{contributing jets}} \mathbf{p}_T^{\text{jet}}$$

The expectation is that $p_T^{\text{hard}} = |\mathbf{p}_T^{\text{hard}}| > 0$ and $\mathbf{p}_T^{\text{hard}} \neq \mathbf{p}_T^{\text{obs}}$. Adding $\mathbf{p}_T^{\text{soft}} = -\mathbf{E}_T^{\text{miss,soft}}$, with $\mathbf{E}_T^{\text{miss,soft}}$ defined in Eq. (6), to $\mathbf{p}_T^{\text{hard}}$ yields an improved estimate of the net transverse momentum carried by undetectable particles, as some of the experimental inefficiencies are mitigated.⁸

In the $Z \rightarrow \mu\mu$ final state without genuine missing transverse momentum the expectation is that $\mathbf{E}_T^{\text{miss}} = -(\mathbf{p}_T^{\text{hard}} + \mathbf{p}_T^{\text{soft}}) = \mathbf{0}$. While this expectation does not hold due to the experimental inefficiencies, it nevertheless raises the expectation that for events without jets $\mathbf{p}_T^{\text{soft}}$ points into the direction of the hadronic recoil, i.e. opposite to $\mathbf{p}_T^{\text{hard}}$ in the transverse-momentum plane. The deviation from this expectation is measured in terms of the parallel (\mathcal{P}_\parallel) and perpendicular (\mathcal{P}_\perp) projections of $\mathbf{p}_T^{\text{soft}}$ onto $\mathbf{p}_T^{\text{hard}}$. Figure 12 schematically shows these projections for $Z+0$ -jet and $Z+1$ -jet topologies.

The average $\langle \mathcal{P}_\parallel \rangle$ in a given bin k of phase space defined by p_T^{hard} measures the $E_T^{\text{miss,soft}}$ response, with $\langle \mathcal{P}_\parallel \rangle = \langle p_T^{\text{hard}} \rangle_k$ indicating a perfect response in this bin. The E_T^{miss} resolution

contribution from $E_T^{\text{miss,soft}}$ reconstruction is measured by two components, the fluctuations in response (RMS_\parallel^2) and the fluctuations of the (transverse) angular deflection around the $\mathbf{p}_T^{\text{hard}}$ axis, measured by RMS_\perp^2 . These fluctuations are expressed in terms of variances, with

$$\text{RMS}_\parallel^2 = \langle (\mathcal{P}_\parallel)^2 \rangle - \langle \mathcal{P}_\parallel \rangle^2 \quad \text{and} \quad \text{RMS}_\perp^2 = \langle (\mathcal{P}_\perp)^2 \rangle.$$

7.1.2 Procedures

The extraction of the systematic uncertainties introduced into the E_T^{miss} measurement by the $E_T^{\text{miss,soft}}$ term is based on data-to-MC-simulations comparisons of $\langle \mathcal{P}_\parallel \rangle(p_T^{\text{hard}})$ for the response, and of $\text{RMS}_\parallel^2(p_T^{\text{hard}})$ and $\text{RMS}_\perp^2(p_T^{\text{hard}})$ for the resolution. Alternative MC samples are considered, with variations of either the event generator or the detector simulation (description and shower models). For the highest impact of $E_T^{\text{miss,soft}}$ on E_T^{miss} , the exclusive $Z \rightarrow \mu\mu$ selection with $N_{\text{jet}} = 0$ is the basis for the determination of the systematic uncertainty components for both data and all MC simulations. In this case, the only hard contribution is from the reconstructed Z boson, i.e. $\mathbf{p}_T^{\text{hard}} = \mathbf{p}_T^Z$ as shown in Fig. 12a.

The uncertainties are determined by comparing \mathcal{P}_\parallel and \mathcal{P}_\perp spectra from data and MC simulations, in bins of p_T^{hard} . For \mathcal{P}_\parallel , the smearing of the response and the width both yield scale and (longitudinal) resolution offsets. In the case of \mathcal{P}_\perp , only smearing of the width is applied to provide transverse resolution offsets. These fitted offsets, determined for the various MC configurations, provide the systematic uncertainties with respect to a specific MC modelling configuration. In practice, to account for the resolution offsets, Gaussian smearing is applied in simulation to the longitudinal and transverse components of $\mathbf{E}_T^{\text{miss,soft}}$ relative to the direction of $\mathbf{p}_T^{\text{hard}}$. To account for differences in response between data and simulation, the longitudinal component of $\mathbf{E}_T^{\text{miss,soft}}$ is scaled up and down to give an uncertainty band.

In order to generate the required number of simulated events, some analyses in ATLAS may have to use the fast detector simulation ATLF2 [38, 45] for the calorimeter response. It employs parameterisations for electromagnetic and hadronic showers, instead of the explicit simulation of the particle tracking through matter and the energy-loss mechanisms in a detailed detector geometry. An additional uncertainty is assigned to effects introduced by ATLF2. This uncertainty contribution only needs to be considered in analyses using this fast simulation, and does not apply for the results presented in this paper. In analyses where it is applicable, it is added in quadrature to the standard uncertainties.

⁸ As discussed in Sect. 3.4, the soft term represents only charged particles with $p_T > 400$ MeV not associated with fully identified and reconstructed particles or jets. Therefore, including $\mathbf{p}_T^{\text{soft}}$ can only recover a part of the actual soft p_T -flow of the interaction.

Fig. 12 Schematic view of the parallel (\mathcal{P}_{\parallel}) and perpendicular (\mathcal{P}_{\perp}) projections of $\mathbf{p}_T^{\text{soft}}$ on $\mathbf{p}_T^{\text{hard}}$ for $Z \rightarrow \mu\mu$ events without genuine E_T^{miss} , for **a** a final state without any jets and **b** a final state with one jet. The

expectation values for a perfect E_T^{miss} reconstruction are $E[\mathcal{P}_{\parallel}] = p_T^Z$ for $N_{\text{jet}} = 0$ and $E[\mathcal{P}_{\parallel}] = p_T^{\text{hard}}$ for $N_{\text{jet}} \geq 1$, with $E[\mathcal{P}_{\perp}] = 0$ in all cases. **a** $Z + 0$ jet topology. **b** $Z + 1$ jet topology

7.2 Systematic uncertainties in E_T^{miss} response and resolution

The result for the systematic uncertainty of the E_T^{miss} scale, determined as discussed in the previous section, is summarised in Fig. 13. The average longitudinal projection of $\mathbf{p}_T^{\text{soft}}$ onto $\mathbf{p}_T^{\text{hard}}$, $\langle \mathcal{P}_{\parallel} \rangle$, as a function of p_T^{hard} is shown in Fig. 13a which compares data to both the standard POWHEG+PYTHIA8-based simulations and the alternative MC simulation employing MADGRAPH, as described in Sect. 4.2. All MC simulation results are expected to have $\langle \mathcal{P}_{\parallel} \rangle_{\text{MC}}$ within the uncertainties of the data. The lower panel of Fig. 13a confirms that the ratio $\langle \mathcal{P}_{\parallel} \rangle_{\text{MC}} / \langle \mathcal{P}_{\parallel} \rangle_{\text{data}}$ lies within the systematic uncertainty band over the full p_T^{hard} range.

The systematic uncertainty for the E_T^{miss} resolution is extracted from the variances of the parallel (RMS_{\parallel}^2) and perpendicular (RMS_{\perp}^2) projections of $\mathbf{E}_T^{\text{miss}}$ onto $\mathbf{p}_T^{\text{hard}}$ defined in Sect. 7.1.2. Figure 13b shows the p_T^{hard} dependence of RMS_{\parallel}^2 measured for the exclusive $Z \rightarrow \mu\mu$ sample ($N_{\text{jet}} = 0$) in data and two MC simulations. The variances $(\text{RMS}_{\parallel}^2)_{\text{MC}}$ calculated for both sets of simulations agree within the systematic uncertainties of $(\text{RMS}_{\parallel}^2)_{\text{data}}$ with the data, as illustrated in the lower panel of the figure, where the ratio $(\text{RMS}_{\parallel}^2)_{\text{MC}} / (\text{RMS}_{\parallel}^2)_{\text{data}}$ is shown as a function of p_T^{hard} . The

results of the evaluation of the variances RMS_{\perp}^2 of the perpendicular projections as a function of p_T^{hard} are shown in Fig. 13c, together with the resulting p_T^{hard} dependence of the ratio $(\text{RMS}_{\perp}^2)_{\text{MC}} / (\text{RMS}_{\perp}^2)_{\text{data}}$. The systematic uncertainties of the data cover all differences to MC simulations.

8 Missing transverse momentum reconstruction variants

8.1 Calorimeter-based E_T^{miss}

The E_T^{miss} soft term from the calorimeter $E_T^{\text{miss,soft,calo}}$ is reconstructed from topo-clusters. As discussed in Ref. [6], each topo-cluster provides a basic EM scale signal as well as a calibrated signal reconstructed using local cell weighting (LCW), and $E_T^{\text{miss,soft,calo}}$ is calculated from topo-clusters calibrated at the LCW scale. Only topo-clusters with a calibrated energy $E_{\text{clus}}^{\text{LCW}} > 0$, not contributing to the reconstruction of the hard objects used to calculate the hard term given in Eq. (6), are considered for $E_T^{\text{miss,soft,calo}}$. In addition, topo-clusters that are formed at the same location as the hard object signals are not considered for $E_T^{\text{miss,soft,calo}}$ even if their signals are not directly contributing to the reconstruction of the hard objects. The fully reconstructed E_T^{miss} using $E_T^{\text{miss,soft,calo}}$ is $E_T^{\text{miss,calo}}$.

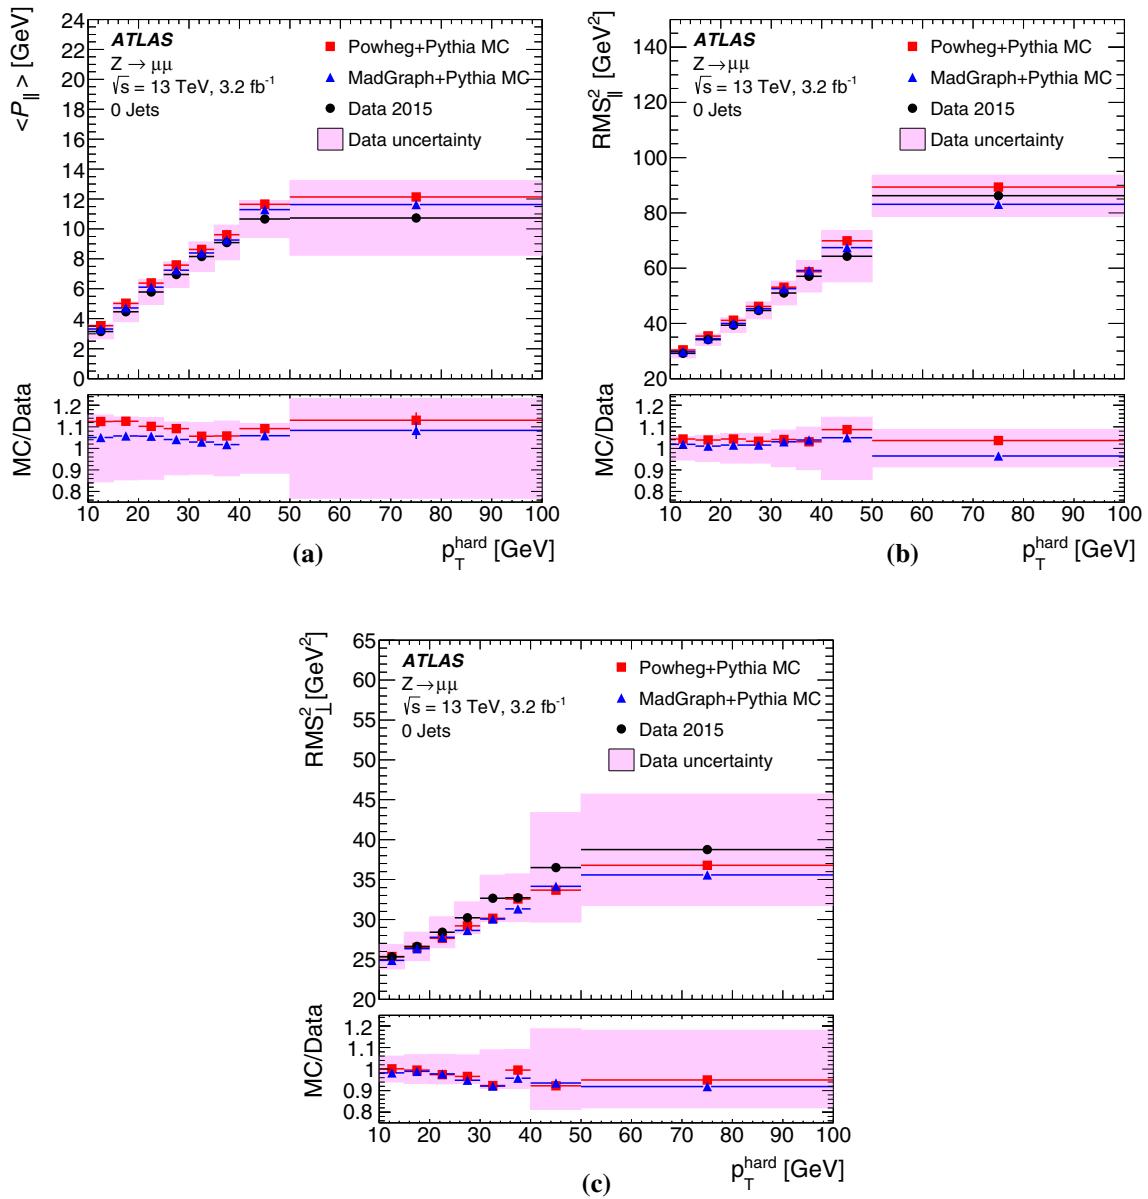

Fig. 13 The **a** average value of the longitudinal projection $\langle \mathcal{P}_{\parallel} \rangle$ and the **b** variance RMS_{\parallel}^2 of the longitudinal projection \mathcal{P}_{\parallel} of $\mathbf{p}_T^{\text{soft}}$ onto $\mathbf{p}_T^{\text{hard}}$ for $Z \rightarrow \mu\mu$ event with $N_{\text{jet}} = 0$, for data and two different MC simulations, shown as a function of p_T^{hard} . The variance RMS_{\perp}^2 of

the perpendicular projection \mathcal{P}_{\perp} is shown in **c** for the same event samples. The shaded band indicates the systematic uncertainties derived as described in the text

Compared to the reference E_T^{miss} and ΣE_T , $E_T^{\text{miss,calo}}$ and ΣE_T^{calo} have an enhanced dependence on pile-up, mostly introduced by the soft term. To partly compensate for the irreducible contribution of p_T -flow reconstructed from topoclusters generated by pile-up to $E_T^{\text{miss,calo}}$, a modified jet selection and ambiguity resolution is applied in their reconstruction. The considered jets are reconstructed following the prescription in Sect. 3.3.5, and required to have a fully calibrated $p_T > 20$ GeV. The contribution of these jets to $E_T^{\text{miss,calo}}$ and ΣE_T^{calo} , defined in terms of momentum compo-

nents (p_x, p_y) , depends on the overlap with already accepted reconstructed particles,

$$(p_x, p_y) = \begin{cases} (0, 0) & \kappa_E \geq 50\% \text{ (large overlap)} \\ (1 - \kappa_E) \times (p_x^{\text{jet}}, p_y^{\text{jet}}) & \kappa_E < 50\% \text{ (small or no overlap)} \end{cases} \quad (14)$$

The overlap fraction κ_E is given in Eq. (8). Jets with $\kappa_E \geq 50\%$ are not used at all. The JVT-based tagging of non-pile-up jets is omitted. It is found that this strategy reduces the fluctuations in the $E_T^{\text{miss,calo}}$ reconstruction. The transverse

momentum contribution of groups of clusters representing a jet-like p_T -flow e.g. from pile-up in a given direction that are not reconstructed and calibrated as a jet, or do not pass the jet- p_T threshold applied in E_T^{miss} reconstruction, is reduced if all jets and jet fragments, including those from pile-up, are included.

8.2 E_T^{miss} from tracks

The reference track-based soft term $E_T^{\text{miss,soft}}$ is largely insensitive to pile-up, as indicated by the dependence of the E_T^{miss} resolution $\text{RMS}_{x(y)}^{\text{miss}}$ on N_{PV} in the exclusive $Z \rightarrow \mu\mu$ sample ($N_{\text{jet}} = 0$) shown in Fig. 7c. As discussed in Sect. 6.2.4 and from the comparison of Fig. 7c, d, the pile-up dependence of $\text{RMS}_{x(y)}^{\text{miss}}$ in the inclusive $Z \rightarrow \mu\mu$ sample is largely introduced by the jet contribution. This contribution suffers from (1) the lack of pile-up suppression for forward jets with $|\eta| > 2.4$, (2) any inefficiency connected with the JVT-based tagging, and (3) irreducible pile-up-induced fluctuations in the calorimeter jet signals. Using a representation of E_T^{miss} employing only reconstructed ID tracks from the primary vertex increases stability against pile-up as long as the tracking and vertex resolution is not affected by it. In this representation (p_T^{miss}) all jets and reconstructed particles are ignored, i.e. the p_T^{miss} reconstruction does not include any calorimeter or MS signals. The p_T^{miss} resolution is then inherently immune to pile-up, while the p_T^{miss} response is low as all neutral p_T -flow in $|\eta| < 2.5$ as well as all p_T -flow outside of this region is excluded.

8.3 Performance evaluations for E_T^{miss} variants

The main motivation to study E_T^{miss} -reconstruction variants is to improve some combination of the E_T^{miss} resolution, scale, and stability against pile-up. As with the composition of objects entering E_T^{miss} reconstruction in general, the particular choice of variant used for a given analysis strongly depends on the performance requirements for this analysis. The comparison of both the resolution and response of $E_T^{\text{miss,calo}}$ and p_T^{miss} to the corresponding measurements using the reference E_T^{miss} illustrates their principal features for the $Z \rightarrow \mu\mu$ and $t\bar{t}$ production final state.

8.3.1 Comparisons of E_T^{miss} resolution

Figure 14 compares the $E_T^{\text{miss,calo}}$ and p_T^{miss} resolutions with the one obtained from the reference E_T^{miss} , for the inclusive $Z \rightarrow \mu\mu$ sample in data. Each is shown as a function of ΣE_T corresponding to the reference E_T^{miss} , giving an estimate of the total hard-scatter activity. The low- ΣE_T region is dominated by events with $N_{\text{jet}} = 0$, where the contribution of $E_T^{\text{miss,soft,calo}}$ in $E_T^{\text{miss,calo}}$ yields a poorer resolution than

Fig. 14 Comparison of the reference E_T^{miss} resolution with the resolutions of the track-only-based variant p_T^{miss} described in Sect. 8.2, and the reconstruction variant $E_T^{\text{miss,calo}}$ employing a calorimeter-based soft term, as discussed in Sect. 8.1. The resolutions are determined as described in Sect. 6.2.3 and shown as a function of the ΣE_T . For consistency, for all three variants, the ΣE_T value is taken from E_T^{miss}

for E_T^{miss} , and where E_T^{miss} and p_T^{miss} have identical performance. The high- ΣE_T region is dominated by events with higher jet multiplicity, where p_T^{miss} resolution is degraded relative to the reference E_T^{miss} by the incomplete measurement of jets.

Figure 15a compares the $E_T^{\text{miss,calo}}$ and p_T^{miss} resolution as functions of the pile-up activity measured by N_{PV} , with the one obtained from the reference E_T^{miss} for the exclusive $Z \rightarrow \mu\mu$ samples with $N_{\text{jet}} = 0$ in data. The $E_T^{\text{miss,calo}}$ resolution is dominated by pile-up and shows significantly degraded performance relative to p_T^{miss} and the reference E_T^{miss} . The exclusive use of only tracks from the hard-scatter vertex for both p_T^{miss} and E_T^{miss} yields the same stability against pile-up.

In events with jet activity, the degraded p_T^{miss} resolution is observable, especially outside the region of highest pile-up activity, as seen in Fig. 15b for the E_T^{miss} resolution obtained with the inclusive $Z \rightarrow \mu\mu$ sample in data for $N_{\text{PV}} \lesssim 15$. This is even more obvious in final states with relatively high jet multiplicity and genuine missing transverse momentum, like for the $t\bar{t}$ -production sample from MC simulations. As shown in Fig. 15c for this final state, both the reference E_T^{miss} and the calorimeter-based $E_T^{\text{miss,calo}}$ have a significantly better resolution than p_T^{miss} , at the price of some sensitivity to pile-up, which is absent for p_T^{miss} . The N_{PV} dependence of the resolution is enhanced in $E_T^{\text{miss,calo}}$, due to the increased contribution from soft calorimeter signals without pile-up suppression at higher N_{PV} .

Fig. 15 Comparison of the reference E_T^{miss} resolution with the resolutions of the track-only-based variant p_T^{miss} described in Sect. 8.2, and the reconstruction variant $E_T^{\text{miss,calo}}$ employing a calorimeter-based soft term, as discussed in Sect. 8.1. The resolutions are determined as described in Sect. 6.2.3 and shown as a function of the pile-up activity

measured in terms of the number of reconstructed vertices N_{PV} for **a** an exclusive $Z \rightarrow \mu\mu$ sample without jets with $p_T > 20 \text{ GeV}$ and **b** an inclusive $Z \rightarrow \mu\mu$ sample, both selected from data. In **c**, the resolution of the E_T^{miss} reconstruction-variants in a final state with significant jet activity and $p_T^{\text{miss}} > 0$ is compared using MC simulations of $t\bar{t}$ production

8.3.2 Comparisons of E_T^{miss} scale

Following the description in Sect. 6.2.1, the E_T^{miss} response is evaluated for the reference E_T^{miss} , $E_T^{\text{miss,calo}}$, and p_T^{miss} using the respective projections of $\mathbf{E}_T^{\text{miss}}$, $\mathbf{E}_T^{\text{miss,calo}}$, and $\mathbf{p}_T^{\text{miss}}$ onto the direction of \mathbf{p}_T^Z , according to Eqs. (9) and (10). Figure 16a shows the average projection as a function of p_T^Z for the exclusive $Z \rightarrow \mu\mu$ sample with $N_{\text{jet}} = 0$ in data. Both E_T^{miss} and p_T^{miss} show the same increasingly incomplete reconstruction of the hadronic recoil in this sample for rising

p_T^Z . This reconstruction is slightly improved for $E_T^{\text{miss,calo}}$, but still insufficient at higher p_T^Z .

In the inclusive $Z \rightarrow \mu\mu$ sample, shown in Fig. 16b, the indication at lower p_T^Z is that $E_T^{\text{miss,calo}}$ has a higher response and thus a better representation of the hadronic recoil, due to the more complete $E_T^{\text{miss,soft}}$ reconstruction and the lack of a JVT-tagging requirement. This effect is partly due to the observation bias in the response introduced by the relatively poor $E_T^{\text{miss,calo}}$ resolution, as discussed in Sect. 3.1. Both E_T^{miss} and $E_T^{\text{miss,calo}}$ show comparable response for

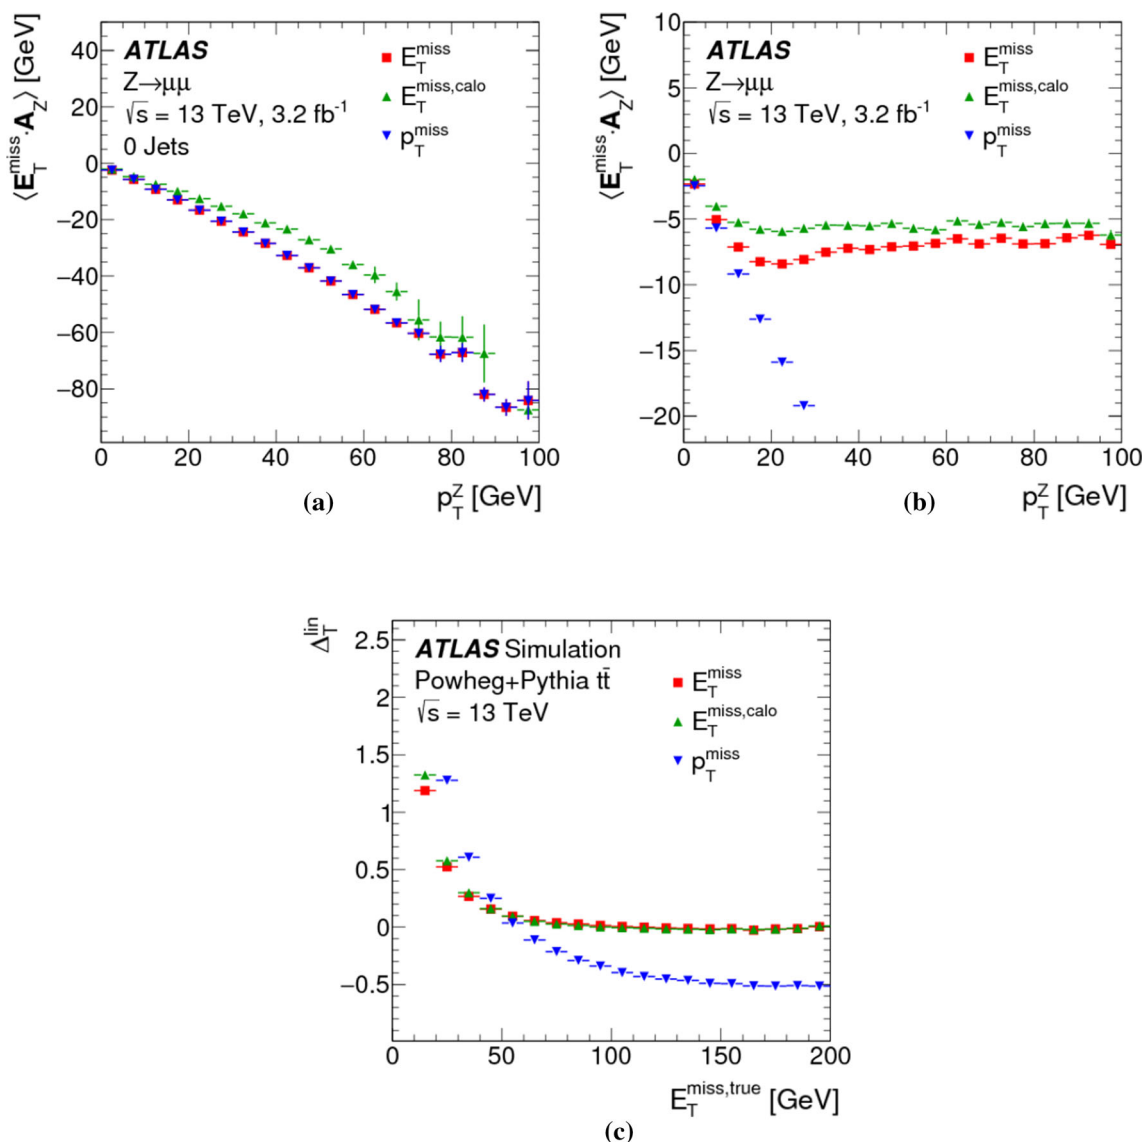

Fig. 16 Comparison of the reference E_T^{miss} , the calorimeter-based $E_T^{\text{miss,calo}}$ and track-only-based p_T^{miss} response in an **a** exclusive and an **b** inclusive $Z \rightarrow \mu\mu$ sample from data. The projections of the respective E_T^{miss} , $E_T^{\text{miss,calo}}$, and p_T^{miss} onto the direction of p_T^Z , calcu-

lated according to Eqs. (9) and (10), are shown as a function of p_T^Z . In **c**, the linearity of the reference E_T^{miss} , $E_T^{\text{miss,calo}}$, and p_T^{miss} scales, calculated according to Eq. (11), is shown as a function of the true $E_T^{\text{miss,true}}$ for the $t\bar{t}$ -production MC simulation sample

$p_T^Z \gtrsim 60$ GeV, owing to the JVT cut-off at 60 GeV. The slightly larger $E_T^{\text{miss,calo}}$ response of about 1 GeV reflects the contribution from neutral signals to the soft term. The degraded response associated with p_T^{miss} related to the exclusion of hard objects is clearly visible in this figure.

Figure 16c shows the linearity of the various E_T^{miss} reconstruction approaches as a function of $E_T^{\text{miss,true}}$ for the $t\bar{t}$ -production sample from MC simulations. Beyond $E_T^{\text{miss,true}} \approx 60$ GeV both the reference E_T^{miss} and $E_T^{\text{miss,calo}}$ show the same good linearity, while the lack of a jet con-

tribution to p_T^{miss} shows a loss of response up to about 50% at higher $E_T^{\text{miss,true}}$. The overestimation of $E_T^{\text{miss,true}}$ by all three reconstruction variants at lower $E_T^{\text{miss,true}}$ reflects the observation bias in the response introduced by the resolution. The poorer resolution associated with p_T^{miss} observed in Fig. 15c for this sample leads to a faster rise of the response with decreasing $E_T^{\text{miss,true}}$ than for the reference E_T^{miss} and $E_T^{\text{miss,calo}}$, which show a very similar dependence on $E_T^{\text{miss,true}}$.

8.3.3 Summary of performance

Both $E_T^{\text{miss,calo}}$ and p_T^{miss} offer alternative measures for E_T^{miss} . The calorimeter-based $E_T^{\text{miss,calo}}$ uses topo-clusters calibrated at the LCW scale for the soft term, which are neither part of the signal nor otherwise overlapping with the signals of other hard objects contributing to E_T^{miss} . This introduces a pile-up dependence into $E_T^{\text{miss,calo}}$, due to the lack of pile-up suppression of calorimeter signals outside of reconstructed hard objects. It features a slightly modified jet contribution without the JVT-based selection used in case of the reference E_T^{miss} reconstruction, to allow the cancellation of jet-like p_T -flow from pile-up in $E_T^{\text{miss,soft,calo}}$ by pile-up jets in its hard term. The $E_T^{\text{miss,calo}}$ response in the inclusive $Z \rightarrow \mu\mu$ sample is better than the reference E_T^{miss} response, in particular in the region of small hadronic recoil ($p_T^Z \lesssim 20$ GeV). It is comparable to the reference in $t\bar{t}$ final states. The observed $\text{RMS}_{x(y)}^{\text{miss}}$, in particular in $Z \rightarrow \mu\mu$ without jets, is significantly more affected by pile-up than is the reference E_T^{miss} or the track-only-based p_T^{miss} . In final states with a considerable number of jets, like $t\bar{t}$, $E_T^{\text{miss,calo}}$ performs nearly as well as the reference E_T^{miss} , with a slight degradation of the E_T^{miss} resolution at highest pile-up activities. This variant is useful for physics analyses least sensitive to the soft-term contribution to E_T^{miss} resolution but requiring a linear E_T^{miss} response.

The track-only-based p_T^{miss} displays a degraded response for the inclusive $Z \rightarrow \mu\mu$ sample, which is expected from the exclusive use of hard-scatter-vertex tracks. As expected, resolution is not affected by pile-up in the considered final states, but is poorer than, or at most comparable to, the reference E_T^{miss} algorithm. Nevertheless, p_T^{miss} provides a stable observable for event and phase-space selections in analyses sensitive to E_T^{miss} resolution.

9 Conclusion

The performance and features of the missing transverse momentum reconstruction in pp collision data at the LHC, acquired in 2015 with the ATLAS detector at $\sqrt{s} = 13$ TeV and corresponding to about 3.2 fb^{-1} , are evaluated for selected event samples with ($W \rightarrow e\nu$, $W \rightarrow \mu\nu$, $t\bar{t}$) and without ($Z \rightarrow \mu\mu$) genuine E_T^{miss} . The comparison of the data from the detector with the corresponding MC simulations generally yields good agreement in the covered phase space. The systematic uncertainty contribution from the soft event to the reconstructed E_T^{miss} is determined with $Z \rightarrow \mu\mu$ final states without jets. It is calculated from the data-to-MC-simulations comparison of the parallel and perpendicular projections of the missing transverse momentum vector $\mathbf{E}_T^{\text{miss}}$ onto the vector sum of the transverse momenta

of the hard objects $\mathbf{p}_T^{\text{hard}}$. The parallel projections yield the uncertainty of the E_T^{miss} scale, evaluated as a function of the total transverse momentum of the hard objects (p_T^{hard}). The widths of the distributions of the parallel and perpendicular projections yield the respective systematic uncertainties of the E_T^{miss} resolution. Simulation tends to underestimate the perpendicular resolution and overestimate the scale and parallel resolution, in each case differing from data by at most 10%.

The performance evaluation of E_T^{miss} response and resolution for the inclusive $Z \rightarrow \mu\mu$ sample shows that data and MC simulations agree within the systematic uncertainties. The E_T^{miss} response shows an underestimation of the soft contributions to E_T^{miss} . A degradation of the E_T^{miss} resolution is observed for increasing ΣE_T and N_{PV} , due to pile-up and detector resolution effects. Additional performance measures considered in these studies include the estimate of tails in the E_T^{miss} distribution. As expected from the universality of the hadronic recoil, the integral tail fraction of the E_T^{miss} distribution is identical for inclusive Z and W boson production, independent of the leptonic decay mode. The $t\bar{t}$ final states feature a higher jet multiplicity and show larger tails reflecting a higher sensitivity to residual pile-up surviving in the jet contribution to E_T^{miss} , in terms of the inclusion of pile-up jets as well as the increased fluctuations of the jet response introduced by pile-up.

From the performance studies presented in this paper, the object-based E_T^{miss} reconstruction in ATLAS, which was developed for LHC Run 1 and used in a large number of physics analyses, can be used with the discussed refinements and adjustments for Run 2 as well.

Appendix A: Glossary of terms

In this paper several acronyms and qualifiers are used to describe the reconstruction of E_T^{miss} and related observables. This brief glossary of terms is intended to help with the nomenclature. All terms should be interpreted in the context of E_T^{miss} reconstruction and may have other interpretations in other contexts.

E_T^{miss} reconstruction: Using this nomenclature usually encompasses the reconstruction of a set of observables comprising the missing transverse momentum vector $\mathbf{E}_T^{\text{miss}}$, its components $E_{x(y)}^{\text{miss}}$, and its absolute value E_T^{miss} . In addition, the scalar sum $\sum E_T$ of the p_T of all kinematic objects contributing to $\mathbf{E}_T^{\text{miss}}$ is calculated. The calculation of these variables is described in detail in Eqs. (1)–(4) in Sect. 3.1.

Hard scatter and primary vertices: The hardest pp interaction in a given event is referred to as the *hard scatter*. It is normally associated with a reconstructed *hard-scatter vertex*, which is considered the hardest vertex among all reconstructed *primary vertices* in this event. The hard-scatter vertex is defined as the one with the largest sum of p_T^2 of tracks associated with it. The other primary vertices are assumed to be produced by in-time pile-up interactions. The variable N_{PV} denotes the number of reconstructed primary collision vertices in the event.

Hard event and hard term: The reconstruction of *hard objects* includes individual particles such as electrons, photons, muons and τ -leptons, and jets. In all cases the final objects are characterised by a kinematic threshold and reconstruction quality requirements. Both the reconstructed charged-particle tracks from the ID and topo-clusters from the calorimeter are used as the input signals for these objects. In the context of E_T^{miss} reconstruction, the use of the same detector signals by different hard objects is excluded, see details in Sect. 3. The finally accepted hard event objects give rise to the *hard term* in E_T^{miss} reconstruction.

Soft event and soft term: All detector signals recorded for one triggered event and not used by the hard objects discussed above can be considered as *soft signals* contributing to E_T^{miss} . They include signals or signal traces from scattered soft particles arising from the underlying event accompanying the hard-scatter interaction, or from statistically completely independent pile-up interactions producing diffuse particle emissions in the same bunch crossing. In addition, signals from particles and jets which do not satisfy the hard-object quality criteria, or are below the kinematic threshold, can be included in the soft event. The reference E_T^{miss} reconstruction configuration for the results presented in Sects. 6 and 7 uses reconstructed ID tracks from the soft event to form the *soft term* in E_T^{miss} reconstruction, with the track selection details outlined under priority (6) in Table 1 in Sect. 3. Alternative configurations employ topo-clusters from the calorimeter, see Table 2 in Appendix A.

Appendix B: Alternative E_T^{miss} composition

Table 2 summarises the E_T^{miss} reconstruction configurations employing only ID tracks, or using topo-clusters for the soft term.

Table 2 Representations of E_T^{miss} and ΣE_T calculated from (1) reconstructed charged-particle tracks from the ID or (2) using a soft term from topo-clusters in the calorimeter only

#	Objects contributing to E_T^{miss} and ΣE_T			
	Type	Selections	Variables	Comments
(1)	ID track	$ \eta < 2.5$ $p_T > 400 \text{ MeV}$ $ d_0 < 1.5 \text{ mm}$ $ z_0 \sin(\theta) < 1.5 \text{ mm}$	p_T^{miss} Σp_T	Charged-particle-based estimators for E_T^{miss} , ΣE_T using all reconstructed tracks from the hard-scatter vertex passing requirements for high-quality reconstruction in addition to kinematic selections
(2)	Topo-cluster	$E_{\text{clus}}^{\text{LCW}} > 0$ (soft term)	$E_T^{\text{miss,soft,calo}}$ $\Sigma E_T^{\text{soft,calo}}$	Variants reconstructing $E_T^{\text{miss,calo}}$ (ΣE_T^{calo}) using a soft term $E_T^{\text{miss,soft,calo}}$ ($\Sigma E_T^{\text{soft,calo}}$) reconstructed from topo-clusters not used by, or not overlapping with, the hard objects used for the hard term composed of items (1)–(5) in Table 1, with the jet selection described in Sect. 8.1 applied

Appendix C: Jet selection

As discussed in Sect. 3.3.5, jets that are not rejected by the signal ambiguity resolution and have $p_T > 60 \text{ GeV}$ contribute to E_T^{miss} reconstruction. Jets with less transverse momentum that fall within $|\eta| < 2.4$ are subjected to further selection based on JVT calculated by a track-based jet vertex tagger [16]. Three values for JVT, each representing a different efficiency for the reconstruction of non-pile-up jets, were considered in the course of the optimisation of the JVT-based selection,

- JVT_{tight} > 0.11 ... tight selection with high pile-up rejection power at lower signal efficiency;
- JVT_{medium} > 0.59 ... medium selection with good signal efficiency and pile-up rejection power;
- JVT_{loose} > 0.91 ... loose selection with lower pile-up rejection power and higher signal efficiency.

The effects of these selections on the E_T^{miss} resolution $\text{RMS}_{x(y)}^{\text{miss}}$ and response are shown in Fig. 17, for $Z \rightarrow \mu\mu$ events in MC simulation. Figure 17a shows that the pile-up dependence of $\text{RMS}_{x(y)}^{\text{miss}}$ is not significantly affected by the choice for JVT. However, the E_T^{miss} response measured by the projection given in Eq. (10) in Sect. 6.2.1 and evaluated as a function of p_T^Z in the same sample, shows significant sensitivity to the choice of JVT, as seen in Fig. 17b.

In addition to the signal ambiguity resolution and the choice for JVT, the contribution from jets in E_T^{miss} reconstruction is controlled by a kinematic threshold requiring the

transverse momentum of the jet to be $p_T > 20 \text{ GeV}$. The effects of variations of this threshold on $\text{RMS}_{x(y)}^{\text{miss}}$ and the E_T^{miss} response are shown in Fig. 18. Increasing the threshold to 30 GeV for all jets satisfying the JVT_{medium} condition reduces the pile-up dependence of the resolution shown in Fig. 17a, but leads to significant loss of E_T^{miss} response, as seen in Fig. 17b. Depending on the sensitivities observed in a given physics analysis, the p_T -threshold choice for the jet contribution to E_T^{miss} reconstruction needs to be adjusted to meet the required performance.

Extending the p_T threshold studies with the option of regional thresholds yields the performance results presented in Fig. 19. In this case jets within $|\eta| < 2.4$ are subjected to the $p_T^{\text{central jet}} > 20 \text{ GeV}$ selection, while jets outside of this η range are filtered using $p_T^{\text{forward jet}} > \{20, 25, 30\} \text{ GeV}$. This leads to the improvements in the pile-up dependence of $\text{RMS}_{x(y)}^{\text{miss}}$ shown in Fig. 19a, which are very similar to the ones observed in Fig. 18a for a global jet- p_T threshold variation. The comparison indicates that the main pile-up contribution to $\text{RMS}_{x(y)}^{\text{miss}}$ is introduced by forward jets, for which no JVT-based pile-up-mitigation is available.

Increasing the p_T threshold only for forward jets reduces the average loss of response observed in case of the global p_T threshold increase. This can be seen by comparing the results shown in Fig. 19b for regional p_T thresholds with the ones shown in Fig. 18b for global thresholds. Like for the JVT threshold selection, the choice of the appropriate global or regional p_T -threshold depends on the E_T^{miss} reconstruction performance required in the context of a given analysis.

Fig. 17 E_T^{miss} resolution and response for the different choices of JVT discussed in the text, as measured for $Z \rightarrow \mu\mu$ events in MC simulation. The **a** E_T^{miss} resolution is shown as function of the pile-up activity measured by the number of primary vertices N_{PV} , and the **b** E_T^{miss} response

is shown as function of the transverse momentum p_T^Z of the Z boson. A global selection of $p_T > 20$ GeV is applied to the transverse momentum of jets within $|\eta| < 2.4$ ($p_T^{\text{central jet}}$) and for forward jets with $|\eta| \geq 2.4$ ($p_T^{\text{forward jet}}$)

Fig. 18 E_T^{miss} resolution and scale for different global jet- p_T thresholds, for $Z \rightarrow \mu\mu$ events in MC simulation. The **a** E_T^{miss} resolution is shown as function of the pile-up activity measured by the number of primary vertices N_{PV} , and the **b** E_T^{miss} response is shown as function

of the transverse momentum p_T^Z of the Z boson. The same respective thresholds are applied to the transverse momentum of jets within $|\eta| < 2.4$ ($p_T^{\text{central jet}}$) and for forward jets with $|\eta| \geq 2.4$ ($p_T^{\text{forward jet}}$), with $p_T^{\text{central jet}}, p_T^{\text{forward jet}} > \{20, 25, 30\}$ GeV

Fig. 19 E_T^{miss} resolution and scale for different regional jet- p_T thresholds, for $Z \rightarrow \mu\mu$ events in MC simulation. The **a** E_T^{miss} resolution is shown as function of the pile-up activity measured by the number of primary vertices N_{PV} , and the **b** E_T^{miss} response is shown as function

of the transverse momentum p_T^Z of the Z boson. The same threshold is applied to the transverse momentum of jets within $|\eta| < 2.4$ ($p_T^{\text{central jet}} > 20$ GeV), while for forward jets with $|\eta| \geq 2.4$ threshold variations ($p_T^{\text{forward jet}} > \{20, 25, 30\}$ GeV) are studied

- ¹⁸¹ Department of Physics, Yale University, New Haven, CT, USA
- ¹⁸² Yerevan Physics Institute, Yerevan, Armenia
- ^a Also at Department of Physics, University of Malaya, Kuala Lumpur, Malaysia
- ^b Also at Borough of Manhattan Community College, City University of New York, NY, USA
- ^c Also at Centre for High Performance Computing, CSIR Campus, Rosebank, Cape Town, South Africa
- ^d Also at CERN, Geneva, Switzerland
- ^e Also at CPPM, Aix-Marseille Université, CNRS/IN2P3, Marseille, France
- ^f Also at Département de Physique Nucléaire et Corpusculaire, Université de Genève, Geneva, Switzerland
- ^g Also at Departament de Física de la Universitat Autònoma de Barcelona, Barcelona, Spain
- ^h Also at Departamento de Física Teórica y del Cosmos, Universidad de Granada, Granada, Spain
- ⁱ Also at Departamento de Física, Pontificia Universidad Católica de Chile, Santiago, Chile
- ^j Also at Departamento de Física, Instituto Superior Técnico, Universidade de Lisboa, Lisbon, Portugal
- ^k Also at Department of Applied Physics and Astronomy, University of Sharjah, Sharjah, UAE
- ^l Also at Department of Financial and Management Engineering, University of the Aegean, Chios, Greece
- ^m Also at Department of Physics and Astronomy, University of Louisville, Louisville, KY, USA
- ⁿ Also at Department of Physics, California State University, Fresno, CA, USA
- ^o Also at Department of Physics, California State University, Sacramento, CA, USA
- ^p Also at Department of Physics, King's College London, London, UK
- ^q Also at Department of Physics, Nanjing University, Nanjing, China
- ^r Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg, Russia
- ^s Also at Department of Physics, Stanford University, USA
- ^t Also at Department of Physics, University of Fribourg, Fribourg, Switzerland
- ^u Also at Department of Physics, University of Michigan, Ann Arbor, MI, USA
- ^v Also at Dipartimento di Fisica E. Fermi, Università di Pisa, Pisa, Italy
- ^w Also at Giresun University, Faculty of Engineering, Giresun, Turkey
- ^x Also at Graduate School of Science, Osaka University, Osaka, Japan
- ^y Also at Horia Hulubei National Institute of Physics and Nuclear Engineering, Bucharest, Romania
- ^z Also at II Physikalisches Institut, Georg-August-Universität Göttingen, Göttingen, Germany
- ^{aa} Also at Institutio Catalana de Recerca i Estudis Avancats, ICREA, Barcelona, Spain
- ^{ab} Also at Institut de Física d'Altes Energies (IFAE), Barcelona Institute of Science and Technology, Barcelona, Spain
- ^{ac} Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany
- ^{ad} Also at Institute for Mathematics, Astrophysics and Particle Physics, Radboud University Nijmegen/Nikhef, Nijmegen, The Netherlands
- ^{ae} Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary
- ^{af} Also at Institute of Particle Physics (IPP), Canada
- ^{ag} Also at Institute of Physics, Academia Sinica, Taipei, Taiwan

- ^{ah} Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan
- ^{ai} Also at Institute of Theoretical Physics, Ilia State University, Tbilisi, Georgia
- ^{aj} Also at Instituto de Física Teórica de la Universidad Autónoma de Madrid, Spain
- ^{ak} Also at LAL, Université Paris-Sud, CNRS/IN2P3, Université Paris-Saclay, Orsay, France
- ^{al} Also at Louisiana Tech University, Ruston, LA, USA
- ^{am} Also at LPNHE, Sorbonne Université, Paris Diderot Sorbonne Paris Cité, CNRS/IN2P3, Paris, France
- ^{an} Also at Manhattan College, New York, NY, USA
- ^{ao} Also at Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia
- ^{ap} Also at National Research Nuclear University MEPhI, Moscow, Russia
- ^{aq} Also at Novosibirsk State University, Novosibirsk, Russia
- ^{ar} Also at O Chadai Academic Production, Ochanomizu University, Tokyo, Japan
- ^{as} Also at Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Freiburg, Germany
- ^{at} Also at School of Physics, Sun Yat-sen University, Guangzhou, China
- ^{au} Also at The City College of New York, New York, NY, USA
- ^{av} Also at The Collaborative Innovation Center of Quantum Matter (CICQM), Beijing, China
- ^{aw} Also at Tomsk State University, Tomsk, and Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia
- ^{ax} Also at TRIUMF, Vancouver, BC, Canada
- ^{ay} Also at Università di Napoli Parthenope, Napoli, Italy
