20 **Abstract**

21 Algae CO<sub>2</sub> biofixation provides a promising opportunity due to earn carbon credits and  
22 valuable end uses. For balancing technology, energy and economy issues in practical  
23 utilization, this approach quantitatively interprets the contradictions from upstream CO<sub>2</sub>  
24 source with a wide range of initial concentration to downstream CO<sub>2</sub> biofixation  
25 product including edible algae and algal biomass. The influence of upstream CO<sub>2</sub>  
26 deliverable on algal quantity and quality have been assessed, and the influence of CO<sub>2</sub>  
27 concentration on CO<sub>2</sub> transport mode choice has been also assessed coupling the  
28 transportation distance. In downstream algal fixation, quantitatively relationship of algal  
29 growth have been established. The assessment discovered that direct energy

30 consumptions complied with logarithmic relationship with specific productivities while  
31 both direct energy and indirect energy consumption complied with linear relationship  
32 with protein content. According to sensitive uncertainty analysis, initial CO<sub>2</sub>  
33 concentration is a critical parameter to influence significantly energy consumption in  
34 upstream CO<sub>2</sub> deliverables and algal quality while the contents of protein and specific  
35 productivity are the critical sensitive parameters in downstream algae deliverables.  
36 Potential modification systems are achieved for significantly reducing energy  
37 consumption by improving specific productivity and carbon abundance with low  
38 protein content in algae.

40 energy consumption

## 41 **1. Introduction**

42 Algae-based CO<sub>2</sub> mitigation provides a promising opportunity to reduce CO<sub>2</sub> and  
43 earns carbon credits due to valuable end uses and lower safety requirement in  
44 comparison with CO<sub>2</sub> storage. As higher efficiency of photosynthesis means higher  
45 carbon dioxide consumption, algae fix CO<sub>2</sub> 10–50 times faster than terrestrial plants by  
46 solar energy (Packer, 2009). Moreover, algae can be cultivated as nutrients for  
47 healthcare (Toledo-Cervantes et al., 2018) or as feedstock for biofuel (Kassim and  
48 Meng, 2017). However, there are lack of the quantitatively assessments to balance  
49 technology, energy and economy issue for fixation product choice of edible algae or  
50 algal biomass.

51 *Spirulina platensis* has been considered as the most promising algae strains to fix  
52 CO<sub>2</sub> due to fast growth rate, good tolerance on high concentration of CO<sub>2</sub> and  
53 insensitive to high temperature, nutrient deficiency and pH flocculation. In addition,  
54 *Spirulina platensis* takes an advantage in economic competitiveness due to highly

55 valuable bioactive compounds with improving the immunity of organism (J. Matos et  
56 al., 2017) and preventing aging (Shabana, et al., 2017).

57 From the respect of algal CO<sub>2</sub> fixation, CO<sub>2</sub> concentration and pollutant  
58 limitation are critical research hotspots (Fu et al., 2019, Ma et al., 2019). Flue gas  
59 from coal power industries and coal chemical engineering activities usually contain a  
60 small amount of SO<sub>x</sub> and NO<sub>x</sub>, which can inhibit algae growth by direct or indirect  
61 toxicity (Negoro, et al.,1991). SO<sub>2</sub> above 60 ppm in flue gas inhibited the growth of  
62 almost all species of microalgae (Zhao, et al., 2014), and all species were completely  
63 inhibited when the flue gas contained SO<sub>2</sub> 200 ppm (Hauck, et al.,1996). Some kinds  
64 of algae have showed good tolerance to NO<sub>x</sub> and some even conducted the limited  
65 positive effect when NO<sub>x</sub> below 300 ppm (Kumar, 2010). However, the dissolution of  
66 NO in the aqueous phase is the rate-limiting step and thus further define NO<sub>x</sub>  
67 concentration in flue gas. CO<sub>2</sub> concentration influences have been controlled pH  
68 flocculation by CO<sub>2</sub> provision but CO<sub>2</sub> absorption efficiencies changed from 75% at  
69 CO<sub>2</sub> 15% to 90% at pure CO<sub>2</sub> (Lundquist et al., 2010). The current research indicates  
70 that CO<sub>2</sub> source as algae cultivation should achieve SO<sub>x</sub> less than 60ppm, NO<sub>x</sub> less  
71 than 300ppm, and NO less than 60ppm but with a wide range of CO<sub>2</sub> concentration.

72 In respect of CO<sub>2</sub> transportation requirement, tanker or pipeline is usually carried  
73 CO<sub>2</sub> in liquid phase except on-site utilization because the volume of liquefied CO<sub>2</sub> is  
74 only 1/500 of CO<sub>2</sub> gas. In order to ensure a stable single-phase flow through the pipeline  
75 for avoiding plug in two-phase flow, CO<sub>2</sub> pipeline with long distance have to be  
76 controlled above CO<sub>2</sub> 95% (Forbes, et al., 2008). For supercritical form, CO<sub>2</sub> should be  
77 further compressed above 8 MPa at ambient temperature (Ancel, et al., 2009) for  
78 reduction of the volume. In order to optimize mass/volume ratio for CO<sub>2</sub> transportation  
79 by pipelines, liquid at pressurized or supercritical conditions is the preferred state for

80 CO<sub>2</sub> as dense phase (Johnsen, et al., 2011). The current research indicated that tankers  
81 are more competitive for shorter distance and lower volume loads while pipelines  
82 transport conduct attractively for high volume load through long distances at wide  
83 deployment.

84 The LCA methodology has been applied to optimize complex system in order to  
85 obtain benefit in environmental, economic and energetic performance. LCA had been  
86 carried out to enhance CO<sub>2</sub> sequestration by storage but less research focuses on algal  
87 biofixation from CO<sub>2</sub> source and its related with the algae quality. Although research of  
88 LCA had been carried out to modify algae product, but most mainly focused on the final  
89 product, such as jet biofuel (Yang, et al., 2016, 2017), biodiesel (Dickinson, et al., 2017),  
90 nutrient (Chensong, et al., 2018). The system boundaries usually initiate from algae  
91 cultivation to algae-related product with CO<sub>2</sub> only as the input of material. There is lack  
92 of the detail discussion of the relationship of upstream of CO<sub>2</sub> capture and purification  
93 to downstream algae in quality and quantity.

94 Whatever the final product of CO<sub>2</sub> fixation is edible algae or algal biomass, a low  
95 energy consumption with an economical feasible system is critical in CCU (Leung, et  
96 al., 2014). The aim of this work is to assess the potential reduction in energy  
97 consumption related with upstream flue gas source to downstream CO<sub>2</sub> fixation product.  
98 The energy consumptions in the whole life cycle have been quantitatively based on  
99 *Spirulina platensis* cultivation. The potential modification systems of CO<sub>2</sub> biofixation  
100 were discussed for reducing the total energy consumption and benefit for biofixation  
101 product choice.

## 102 **2. Methodology**

### 103 *2.1 Goal definition and system boundary*

104 To obtain benefits in energy consumption and algae in quantity and quality, the

105 boundary of life cycle started from CO<sub>2</sub> source with a wide range of initial  
106 concentration and terminated at CO<sub>2</sub> biofixation product including edible algae and  
107 algal biomass, given in Fig. 1. The functional units were set at energy consumption per  
108 kilogram of carbon dioxide fixation (MJ/ kgCO<sub>2</sub>) and energy consumption per  
109 kilogram of algae (MJ/ kg algae) in life cycle assessment.

110

111 Fig. 1. System boundary definition of CO<sub>2</sub> algal fixation

112

113 For edible algae, CO<sub>2</sub> source after purification for algae cultivation should match  
114 edible safety requirements. For algal biomass, CO<sub>2</sub> source should achieve algal  
115 growth requirement. The purification of CO<sub>2</sub> source should comply with the  
116 requirement of CO<sub>2</sub> transportation, including low pressure pipeline, pressured  
117 pipeline, supercritical pipeline, heavy duty truck, and medium duty truck.

118 In compliance of CO<sub>2</sub> as basic substance flow in life cycle, the system boundary  
119 was classified into 4 stages, including CO<sub>2</sub> capture and purification, CO<sub>2</sub> transport,  
120 CO<sub>2</sub> distribution and absorption, and CO<sub>2</sub> biofixation product. The input and the  
121 output of energy and material have been involved in the system.

## 122 2.2 Computational framework and methods

123 The computational framework contains sub-models based on 4 stages including  
124 CO<sub>2</sub> capture and purification, CO<sub>2</sub> transport, CO<sub>2</sub> distribution and absorption (algae  
125 cultivation), and CO<sub>2</sub> fixation (*Spirulina platensis*).

126 In sub-model of CO<sub>2</sub> capture and purification, flue gas with a wide range of CO<sub>2</sub>  
127 concentration were captured and purified to edible requirement or algal cultivation  
128 requirement by technologies including absorption, adsorption, member separation,  
129 and cryogenic distillation. In sub-model of CO<sub>2</sub> transport, feasible transportation  
130 modes are involved in this study including tankers and pipelines related with the

131 distance and CO<sub>2</sub> concentration. In sub-model of CO<sub>2</sub> distribution & absorption,  
132 raceway pond and photobioreactor are chosen to cultivate *Spirulina platensis* for CO<sub>2</sub>  
133 absorption. In sub-model of CO<sub>2</sub> fixation product, edible algae or algal biomass, can  
134 be obtained by a series of processes including harvesting by coagulation or floatation,  
135 further dewatering by press filter or centrifuge, and dry by thermal spray.

136 The following setups have been conducted in the model based on practical industry  
137 and basic theory. CO<sub>2</sub> transport is set up 99% efficiency despite by truck and by pipeline.  
138 Nutrients are supplement to be consumed stoichiometrically based on element ratio of  
139 carbon: nitrogen: phosphorus (C: N: P) in *Spirulina platensis* with around 5% N-  
140 nutrient loss in volatilization. Although the media usually contain excess nutrient  
141 concentrations relative to the algae concentration, the nutrient consumption is only  
142 considered as the supplement due to water recycled. The harvesting section chose  
143 dewatering by coagulation deposit while further dewatering chose press filter to obtain  
144 slurry in compliance with the characteristic of *Spirulina platensis*. *Spirulina platensis*  
145 slurry was conducted to algae powder by an industrial spray dryer.

### 146 2.3 Life cycle inventory data

147 In stage 1, LCI data on CO<sub>2</sub> capture and purification from flue gas with CO<sub>2</sub> 10%  
148 - 15% derived from coal power station industries and CO<sub>2</sub> 10%-99% derived from  
149 coal chemical industries, have been collected from literature (Zhang, et al., 2016) and  
150 practical industries. The energy consumption of CO<sub>2</sub> purification by cryogenic  
151 fractionation were obtained from literature (Liu X, et al., 2015), which have been  
152 simulated based on mathematics model, seen in section 3.1.

153 In stage 2, CO<sub>2</sub> transport mode including pipeline and ground tanker by truck  
154 have been collected from literature (Abbas, et al., 2013; Gao, et al., 2011). The LCI  
155 data for pipeline is derived from literature (Khoo, et al., 2006), which points that some

156 additional energy is required for recompression of CO<sub>2</sub> due to the pressure drop. The  
157 LCI data for ground tanker by truck is derived from Greet (Argonne National  
158 Laboratory, 2018).

159 In stage 3 of CO<sub>2</sub> distribution and absorption (algae cultivation), the LCI data of  
160 raceway pond was collected by the actual *Spirulina platensis* powder production plant  
161 in China. The data of raceway ponds and other photobioreactor were collected (Das, et  
162 al.,2012; Frank, et al., 2012). The energy consumption for pumping CO<sub>2</sub> is related with  
163 the type of bioreactor and the depth of bioreactor. The mixing energy demand is  
164 proportional to the entire volume and algae density. CO<sub>2</sub> absorption efficiency in  
165 raceway pond was considered in the range of 75 - 90% (Lundquist et al., 2010) due to  
166 a small amount release into air.

167 In stage 4 of CO<sub>2</sub> fixation product, LCI data was derived from algae powder  
168 production plant in China. Due to cultivation scale and characteristics of *Spirulina*  
169 *platensis*, coagulation deposit is used to reduce the concentration of water and results  
170 in the solid content from 0.5% to 5.0-6.0 %. The solid content of *Spirulina platensis*  
171 increases to 18% - 20% by press filtration while the solid content increases to 20 %-  
172 22% by centrifuge. *Spirulina platensis* slurry was further dried to obtain *Spirulina*  
173 *platensis* powder (80%) through thermal spray with the energy consumption at heat  
174 provision.

### 175 **3. Results and discussion**

#### 176 **3.1 Effects of CO<sub>2</sub> deliverables quality on algal product**

177 CO<sub>2</sub> deliverables should comply with CO<sub>2</sub> source as edible requirement  
178 considering algae as the feed or the health care while as algae growth requirement  
179 considering algae as biomass for CO<sub>2</sub> fixation.

180 For algal growth requirement, CO<sub>2</sub> source should achieve SO<sub>x</sub> ≤ 60ppm, NO<sub>x</sub>

181  $\leq 300$ ppm, and  $\text{NO} \leq 60$ ppm for algal biomass. For long distance transportation by  
182 tanker or as purely as edible requirement,  $\text{CO}_2$  purification needs to be confined as  
183 liquid phase with  $\text{CO}_2 > 95\%$ ,  $\text{H}_2\text{S} < 2\%$ ,  $\text{N}_2 < 2\%$ ,  $\text{CH}_4 < 2\%$ ,  $\text{H}_2\text{O} < 0.24\text{g/m}^3$ . Four  
184 typical technologies of  $\text{CO}_2$  capture and purification can be applied to provide  $\text{CO}_2$   
185 deliverables for algal biomass while only cryogenics process can achieve to provide  
186  $\text{CO}_2$  deliverables for edible algae, shown in Fig.2.

187

188 Fig.2 Energy consumption in  $\text{CO}_2$  capture and purification

189 a.  $\text{CO}_2$  deliverables for algae biomass; b. edible  $\text{CO}_2$  deliverables

190

191 From the respect of  $\text{CO}_2$  deliverables for algal biomass, shown in Fig.2(a), the  
192 energy consumptions in chemical absorption for capturing  $\text{CO}_2$  were estimated at 1.19–  
193 1.22 MJ/kg  $\text{CO}_2$  coupling with heat requirements and solvent regeneration. In physical  
194 swing adsorption, the energy consumptions in capturing flue gas are estimated to be  
195 0.58-0.66 MJ/kg  $\text{CO}_2$  with 85 % - 90% recovery efficiency. In membrane separation,  
196  $\text{CO}_2$  in the flue gas can pass through the membrane wall and results in isolating  
197 impurities by commercial polymeric gas separation membranes with energy  
198 consumption 0.25-0.27 MJ/kg  $\text{CO}_2$  at typical removal rates 82%-88%. In cryogenic  
199 fractionation, flue gas is cooled  $\text{CO}_2$  in liquid phase and subsequently separated from  
200 other impurities.  $\text{CO}_2$  recovery efficiency can reach approximately 90%-95% with  
201 purified 99.9%  $\text{CO}_2$ . Since the process is conducted at extremely low temperature and  
202 high pressure, it is an energy intensive process and the energy consumption is related  
203 with the freezing point, which is further related significantly with concentration of  $\text{CO}_2$   
204 in the flue gas and compositions of impurities. For the view of  $\text{CO}_2$  deliverable for algal  
205 biomass, the membrane separation performs the lowest energy consumption in

206 comparison with the chemical absorption and physical swing adsorption.

207 From the respect of CO<sub>2</sub> deliverables for edible algae, only cryogenics can comply  
208 with CO<sub>2</sub> source as purely as edible requirement. Energy consumptions in cryogenics  
209 technology are closely related with initial CO<sub>2</sub> concentration and pressure, which  
210 decrease with the increase of initial pressure and the increase of initial CO<sub>2</sub>  
211 concentration, shown in Fig.2(b). The effects of initial pressure on energy consumption  
212 decrease with the increase of initial CO<sub>2</sub> concentration. As a result, cryogenics is much  
213 more appropriate for CO<sub>2</sub> capturing and purification with high initial CO<sub>2</sub> concentration  
214 and pressure. Moreover, the concentration of CO<sub>2</sub> purification can achieve above 95%  
215 for transportation in long distance.

216 CO<sub>2</sub> source for transportation is required not only to prevent corrosion and other  
217 defects in pipelines or tankers but also to keep a stable single-phase flow because of the  
218 impurities on the boundaries of pressure and temperature envelope. Therefore, CO<sub>2</sub>  
219 capture and purification should comply with the requirement of algae product quality  
220 and CO<sub>2</sub> transportation. Low pressure pipeline and pressured pipeline can be used to  
221 transport CO<sub>2</sub> with wide range of concentration, but the energy consumptions decreased  
222 exponentially with the increase of CO<sub>2</sub> concentration in pipeline transportation, given  
223 in Fig.3. Supercritical pipeline and truck can be only used on transport with above 95%  
224 CO<sub>2</sub>. For flue gas with above 95% CO<sub>2</sub>, trucks take an advantage in energy consumption  
225 in comparison with pipelines.

226

227 Fig. 3 Energy consumption in CO<sub>2</sub> transportation

228

### 229 ***3.2 Effects of algae growth rate and protein contents on energy consumption***

230 Direct energy consumption in algae cultivation including CO<sub>2</sub> distribution,  
231 power for algae suspension, power for pumping nutrient and water provision. Indirect  
232 energy consumption mainly takes place on nutrient consumption as P and N resource.  
233 The growth rate and content of *Spirulina platensis* are mainly influenced by  
234 controllable parameters and uncontrollable parameters. Controllable parameters  
235 contain CO<sub>2</sub> distribution, pH, and nutrient concentrations, which keep artificially at  
236 optimization condition, while uncontrollable parameters contain radiation and  
237 temperature, which usually control at the optimization condition in lab scale but  
238 depend on the geographical conditions in practical scale.

239 The effects of specific productivity and algae contents on energy consumption  
240 were assessed quantitatively, given in Fig.4(a). Direct energy consumptions were  
241 related with specific productivities in compliance with logarithmic relationship. The  
242 empirical equations of direct energy consumptions with specific productivities and  
243 algal contents are established as following:

$$244 Y_{alage} \text{ (energy consumption, MJ/kg algae)} = - 0.951 \ln[x] + 3.7258 \quad [1]$$

$$245 Y_{CO_2} \text{ (energy consumption, MJ/kg CO}_2\text{)} = (- 0.564 \sim - 0.659) \ln[x] + 2.2074 \quad [2]$$

246 Where x is specific productivity and Y is energy consumption.

247 The results indicated that direct energy consumption based on algae growth is only  
248 the function of specific productivity, given in equation [1]. The direct energy  
249 consumption based on algae yield can reduce by 58% with the increase of the specific  
250 productivity from 14 g/m<sup>2</sup>.d to 24 g/m<sup>2</sup>.d. However, direct energy consumptions based  
251 on CO<sub>2</sub> biofixation are the function of specific productivity and carbon content in algae,

252 given in equation [2]. Although direct energy consumptions based on CO<sub>2</sub> biofixation  
253 reduce with the increase of the specific productivity, the high protein content with low  
254 carbohydrate can also benefit in energy consumptions based on CO<sub>2</sub> biofixation due to  
255 higher carbon abundance in algae. The results indicate that the reduction of direct  
256 energy consumption in CO<sub>2</sub> biofixation should improve the specific productivity and  
257 carbon abundance in algae.

258 Considering both direct and indirect energy consumption, given in Fig.4(b), energy  
259 consumptions increase with protein content in compliance with linear relationship.  
260 When diammonium hydrogen phosphate is used as nutrient for supplement of P and N  
261 resource, indirect energy consumption derived from nutrient input can deduce with the  
262 decrease of protein content and keep at 16% protein content. Further reduction of  
263 protein content cannot reduce the indirect energy consumption of nutrient due to the  
264 restriction of P resource requirement. Indirect energy consumptions are in the range of  
265 0.292-3.219 MJ/kg CO<sub>2</sub> while direct energy consumptions are in the range of 0.427-  
266 0.855 MJ/kg CO<sub>2</sub>. The results indicate that the reduction of protein content could get  
267 the benefit in the reduction of energy consumption.

268

269 Fig.4 Energy consumption in biofixation related with specific productivity and  
270 content a. direct energy consumption; b. direct and indirect energy consumption

271

### 272 ***3.3 Sensitive analysis of uncertainty parameters in life cycle***

273 For further reduction the energy consumption and modification the system, the  
274 key impact factors should be extracted for modification. The sensitive uncertainty  
275 analysis of whole life cycle has been assessed quantitatively, given in Fig. 5.

276

277

Fig.5 Sensitive analysis of uncertainty parameters

278

a. edible algae (protein 65%, initial CO<sub>2</sub> 98%, specific productivity 20g/m<sup>2</sup>.d);

279

b. algal biomass (protein 20%, initial CO<sub>2</sub> 15%, specific productivity 20g/m<sup>2</sup>.d)

280

281

Despite edible algae or algal biomass, shown in Fig. 5(a) and (b), protein

282

contents perform the most sensitive to energy consumption. The high protein contents

283

lead to the increase of nutrient consumption and subsequently results in high indirect

284

energy consumption. The energy consumption of nutrient consumption occupied 94%

285

at protein 65.3% and 13.5 % at protein 10% while occupied 24.1 % at protein 65.3%

286

and 2.41 % at protein 10% in comparison with total energy consumption of algae

287

slurry.

288

Another sensitive uncertainty parameter is related with CO<sub>2</sub> capture and

289

purification. For edible algae, the sensitive uncertainty parameter is in cryogenic

290

process related with initial CO<sub>2</sub> concentration and pressure of CO<sub>2</sub> source. For algal

291

biomass, the choice of purification method influences mainly the energy consumption.

292

Specific productivity of algal biomass conducted more sensitive to energy

293

consumption than edible algae. The energy consumption on algal biomass cultivation

294

occupied 40% at 14 g/m<sup>2</sup>.d and 28 % at protein 24 g/m<sup>2</sup>.d while on edible algae

295

occupied 13.1% at 14 g/m<sup>2</sup>.d and 8.1% at protein 24 g/m<sup>2</sup>.d in comparison with total

296

energy consumption of algae slurry. The absorption efficiency is not sensitive to

297

energy consumption in both life cycle of edible algae and algal biomass.

298

### 3.4 Optimizing CO<sub>2</sub> biofixation system

299

For achieving the reduction of energy consumption, the energy consumptions in

300

life cycle from CO<sub>2</sub> source to CO<sub>2</sub> fixation product, are modified stage by stage

301

according to final products of edible *Spirulina platensis* slurry and powder, as well as

302 *Spirulina platensis* slurry and powder, given in Fig.6.

303

304 Fig.6 Energy consumption in whole life cycle

305 a. edible algae; b. algal biomass

306

307 Algal biomass can reduce 2.52 MJ/kg CO<sub>2</sub> in the total energy consumptions  
308 compared with final products of edible algae at same level of protein content with same  
309 specific productivity. The reason is mainly at stricter CO<sub>2</sub> purification requirement for  
310 edible algae, which can only use completed purified CO<sub>2</sub> but algal biomass can use CO<sub>2</sub>  
311 in a wide range. For flue gas with 15% CO<sub>2</sub>, the possible transportations conduct 0.0587  
312 MJ/kg.km by low pressure pipeline and 0.086 MJ/kg.km by pressured pipeline.  
313 Moreover, some additional energy is required for recompression of CO<sub>2</sub> per 100 km  
314 due to the pressure drop. For above 100 km transportation distance and cryogenics in  
315 compliance with long distance transportation, energy consumption enhanced largely in  
316 CO<sub>2</sub> purification and transportation. Although member separation performs the lowest  
317 energy consumption while cryogenics conduct the highest energy consumption,  
318 cryogenics can obtain liquid CO<sub>2</sub> while the others get condensed CO<sub>2</sub> gas and can  
319 comply with CO<sub>2</sub> transportation requirement on long distance, the energy consumption  
320 of which is closely related with initial CO<sub>2</sub> concentration. Flue gas with 15% CO<sub>2</sub> is  
321 available for on-site biofixation and cultivate algal biomass. Flue gas with above CO<sub>2</sub>  
322 90% is available for long distance biofixation and cultivate edible algae. The method  
323 of capture and purification related with concentration of CO<sub>2</sub> source is the crucial  
324 parameters to influence the quality of algae.

325 From the view of algae cultivation just for CO<sub>2</sub> fixation, the protein content can  
326 further decrease around 16% for reduction of indirect energy consumption while the

327 specific productivity and carbon abundance in algae improve for reduction of direct  
328 energy consumption. The optimization of energy consumptions in CO<sub>2</sub> biofixation  
329 stage can reduce to around 0.72 MJ/kg CO<sub>2</sub>.

330 Considering the final phase as powder, the crucial energy consumption unit is in  
331 the dry process, which cost 14.88 MJ/kg algae, which indicate that algae slurry should  
332 be further developed to put directly practical use such as fish food due to the reduction  
333 of energy consumption in comparison with algae powder. Coupling optimization in the  
334 energy consumption of the whole life cycle, the total energy consumptions can reduce  
335 to 1.49 MJ/kg CO<sub>2</sub> for *Spirulina platensis* slurry while can reduce to 2.69 MJ/kg CO<sub>2</sub>  
336 for edible *Spirulina platensis* slurry at low protein level.

337 From the view of economy, the protein in edible algae should usually keep at high  
338 level above 60% as healthcare product. Accordingly, indirect energy consumption  
339 derived from nutrient supplement should cost at least 4.89 MJ/kg algae, namely 2.94  
340 MJ/kg CO<sub>2</sub>. Moreover, as CO<sub>2</sub> purification requirement for edible food, the energy  
341 consumption derived from purification of flue gas source above 95% CO<sub>2</sub> concentration  
342 should cost at least 0.59 MJ/kg CO<sub>2</sub>. The total energy consumptions cost at least at 4.24  
343 MJ/kg CO<sub>2</sub> (7.04 MJ/kg algae) for edible *Spirulina platensis* slurry and 13.71 MJ/kg  
344 CO<sub>2</sub> (22.75 MJ/kg algae) for edible *Spirulina platensis* powder.

#### 345 **4. Conclusions**

346 The correlation among carbon dioxide concentration in flue gas, microalgae quality,  
347 yield and carbon sequestration were established in the whole life cycle of carbon  
348 sequestration.

349 CO<sub>2</sub> capture and purification should comply with the requirement of algae product  
350 quality and CO<sub>2</sub> transportation. Flue gas with 15% CO<sub>2</sub> is appropriate for on-site  
351 biofixation and cultivate algal biomass while flue gas with above CO<sub>2</sub> 90% is available

352 for long distance biofixation and cultivate edible algae.

353 The empirical equations of direct energy consumptions with specific productivities  
354 and algal contents are established in algae cultivation stage. The results indicated that  
355 direct energy consumption based on algae growth is only the function of specific  
356 productivity while direct energy consumptions based on CO<sub>2</sub> biofixation are the  
357 function of specific productivity and carbon content in algae. As energy consumptions  
358 increase with protein content in compliance with linear relationship, protein contents  
359 play an important role in energy consumption of CO<sub>2</sub> fixation despite edible algae or  
360 algal biomass.

361 Algal biomass can reduce 2.52 MJ/kg CO<sub>2</sub> in the total energy consumptions  
362 compared with final products of edible algae at same level of protein content with same  
363 specific productivity.
