Abstract

Objective: To establish the feasibility of a multicentre randomised controlled trial to assess the effectiveness and cost-effectiveness of a non-operative treatment pathway compared to appendicectomy in children with uncomplicated acute appendicitis.

Design: Feasibility randomised controlled trial with embedded qualitative study to inform recruiter training to optimise recruitment and the design of a future definitive trial

Setting: Three specialist paediatric surgery centres in the United Kingdom

Patients: Children (aged 4-15 years) with a clinical diagnosis of uncomplicated acute appendicitis

Interventions: Appendicectomy or a non-operative treatment pathway (comprising broad-spectrum antibiotics and active observation)

Main outcome measures: Primary outcome measure was the proportion of eligible patients recruited. Secondary outcomes evaluated adherence to interventions, data collection during follow-up, safety of treatment pathways and clinical course.

Results: Fifty percent of eligible participants (95%CI 40-59) approached about the trial agreed to participate and were randomised. Repeated bespoke recruiter training was associated with an increase in recruitment rate over the course of the trial from 38% to 72%. There was high acceptance of randomisation, good patient and surgeon adherence to trial procedures and satisfactory completion of follow-up. Although more participants had perforated appendicitis than had been anticipated, treatment pathways were found to be safe and adverse event profiles acceptable.

Conclusion: Recruitment to a randomised controlled trial examining the effectiveness and cost-effectiveness of a non-operative treatment pathway compared to appendicectomy for the treatment of uncomplicated acute appendicitis in children is feasible.
Introduction

Acute appendicitis is the most common surgical emergency in children and is most frequently treated with appendicectomy. Recently non-operative treatment of appendicitis (with antibiotics alone and without an appendicectomy) has come to the fore as an alternate treatment approach but has not yet entered mainstream clinical practice. Barriers to the more widespread adoption of non-operative treatment include concerns over safety and efficacy and the fact that many surgeons are unfamiliar with this treatment strategy. Although appendicectomy is a tried and tested treatment, is familiar to surgeons and has a well-understood safety and efficacy profile, it does require a general anaesthetic and an abdominal operation with inherent risks. Many parents find the proposal that their child needs emergency surgery frightening and one they are keen to avoid if a viable alternative is available. Whilst the existing evidence supports the safety of non-operative treatment(2) there is an evidence gap preventing meaningful comparison of the effectiveness and cost effectiveness of these treatment approaches;(2) in particular there is a lack of well-designed randomised controlled trials comparing appendicectomy with non-operative treatment.

In order to conduct an adequately powered pragmatic RCT, we first identified the need for further information on the feasibility of recruiting children to a RCT comparing appendicectomy with non-operative treatment. Issues to consider include: a lack of experience with non-operative treatment of acute appendicitis in the UK, so that surgeons may not be willing to recruit, and a challenging trial recruitment profile. Specifically such a trial would involve recruiting children presenting acutely (often out of normal working hours), explaining a trial that has two very different treatment pathways in a time-limited setting, and relying on clinical staff with little trials experience to recruit to the trial in an unscheduled care setting. Furthermore, we identified several uncertainties regarding the design of a definitive effectiveness trial, not least the selection of appropriate primary and secondary outcomes.

We therefore performed a feasibility RCT with an embedded qualitative study. The aims were (i) to test feasibility of recruitment to an RCT of acute uncomplicated appendicitis in children in the UK, from both a patient and surgeon perspective; (ii) to optimise recruitment into the trial; (iii) to confirm the performance and safety of treatment pathways and (iv) to inform the design of a future definitive RCT. The detailed methods and results of the embedded qualitative study are reported elsewhere.(3) The feasibility RCT was part of the CONservative TReatment of Appendicitis in Children randomised controlled Trial (Feasibility) study that also included the development of a core outcome set for research involving children with uncomplicated appendicitis to identify outcomes important to a range of stakeholders, and a health economic feasibility study (both reported elsewhere).(4-6)
we report key outcomes from the feasibility trial, which inform the viability of a future RCT, and key related findings from the embedded qualitative study.

**Methods**
This feasibility RCT comparing appendicectomy and non-operative treatment in children with uncomplicated acute appendicitis was conducted in three specialist paediatric surgery centres in England and in accordance with a publicly available protocol.(7)

**Participants**
Children age >3 and <16 years with a clinical diagnosis, with or without radiological assessment, of uncomplicated acute appendicitis which prior to study commencement would be treated with appendicectomy, were eligible for inclusion. Exclusion criteria were: clinical signs or radiological findings to suggest perforated appendicitis; presentation with appendix mass; previous episode of appendicitis or appendix mass treated non-operatively; major anaesthetic risk precluding allocation to the appendicectomy arm; a known antibiotic allergy preventing allocation to non-operative treatment arm; antibiotic treatment started at referring institution (defined as 2 or more doses administered); cystic fibrosis; a positive pregnancy test, or current treatment for malignancy. Of note there was no requirement for diagnostic imaging in this study since imaging is not routinely used in the diagnostic evaluation of children suspected to have appendicitis in the UK(8) (9) and we wished to replicate current diagnostic pathways and deliver a pragmatic trial as far as possible.

**Participant identification, recruitment, randomisation**
Participants were identified by the clinical team at the time of diagnosis and eligibility was confirmed by the research team as soon as possible. Eligible patients were approached by the treating clinical teams with support from dedicated research nurses. Potential participants were provided with written information about the study and shown a short video describing the study (available at http://tinyurl.com/contract-f). From the time of first discussing the trial with potential participants and their families a maximum of four hours was permitted before a decision could be made regarding participation. This was to ensure there was no delay in providing treatment as a result of considering trial participation.

After written informed consent (and assent from children aged 12 years or over who wished to give it), a member of the trial team randomised the participant to one of two treatment groups in a 1:1 ratio via an independent web-based system, minimising for recruiting centre, sex [male/female], age [4-8/9-15] and duration of symptoms (onset of pain to recruitment into study) [<48 hours/ ≥48
hours], with complete pre-randomisation concealment of treatment allocation. Participants were informed of their treatment allocation immediately.

**Interventions**

*Non-operative treatment arm*

Children randomised to non-operative treatment were treated according to a clinical pathway designed specifically for this trial: fluid resuscitation, a minimum of 24 hours broad spectrum Intravenous (IV) antibiotics (per local antimicrobial policy), a minimum of 12 hours nil by mouth (NBM) and regular clinical review to detect signs and symptoms of significant clinical deterioration (including, but not limited to, increasing fever, increasing tachycardia, and increasing tenderness). After the initial 12-hour period of NBM, oral intake was advanced as tolerated. Children successfully treated without an operation were converted to oral antibiotics (per local policy) once they are afebrile for 24 hours and tolerating oral intake.

Clinical reviews were completed at approximately 24 and 48 hours post randomisation. Any children who showed signs of significant clinical deterioration by 24 hours, or at any point during the trial, were treated with appendicectomy. Children who were considered stable or improving continued with non-operative treatment. At 48 hours, any child who had not shown clinical improvement was scheduled for an appendicectomy. The decision to continue non-operative treatment at these time points or to recommend discontinuation of non-operative treatment and appendicectomy, was made by the treating consultant based on clinical judgement. All reasons for change in treatment were recorded in detail in order to guide a clinical pathway in a future trial.

Any child who received an appendicectomy for an incomplete response to non-operative treatment, followed a standardised post-operative treatment regime already in use at each institution and identical to that used in the appendicectomy arm. The reason for having an appendicectomy was recorded.

Children treated non-operatively received a total of 10 days antibiotics following randomisation unless decided otherwise by the treating clinician. Children who received non-operative treatment were not offered interval appendicectomy, but were counselled about the risk of recurrence.

*Appendicectomy treatment arm*

Children randomised to the appendicectomy arm underwent either open or laparoscopic appendicectomy at the surgeon’s discretion, performed by a suitably experienced trainee (as per routine current practice) or a consultant. Participants received IV antibiotics from the time of diagnosis and were treated post-operatively with IV antibiotics according to existing institutional
protocols. The duration of antibiotic therapy was not standardised due to anticipated variation in intra-operative findings and in response to treatment. The type of antibiotics used was identical to those used in the non-operative treatment arm within each centre. Any child failing to respond to first line antibiotics was treated as clinically appropriate with a longer course of antibiotics or a change in antibiotic therapy determined by intra-operative swab or fluid culture. Post-operatively, children with uncomplicated acute appendicitis or a normal appendix did not routinely have a nasogastric tube, nor a urinary catheter. They received oral intake as tolerated after surgery. The clinical pathway for the two treatment arms is shown in Figure 1. The schedule of enrolment, interventions and follow-up has been previously reported.(7)

Discharge assessment

Criteria for discharge home were the same in each treatment arm: vital signs within normal limits for age, afebrile for ≥ 24 h, tolerating light diet orally, adequate oral pain relief and able to mobilise. Parents of all participants were given an information sheet at discharge informing them of ‘red flag’ symptoms and advised to contact their local unit if they had concerns about their child’s clinical progress.

Follow-up and data collection

Participants were asked to complete a diary card for the first 14 days following hospital discharge about: medication taken (antibiotics and analgesia), whether they had been able to return to normal activity or full activity that day and if their parent(s) had had to take time off work because of their appendicitis. A clinic follow-up visit took place at 6 weeks with further trial follow-up at 3 and 6 months following discharge, either in the outpatient clinic or in the clinical research facility at each centre. If a face-to-face appointment was not possible, the 3- and 6-month follow-up were completed by telephone. Data were recorded by dedicated research nurses at each site during hospital admissions and trial follow-up directly into an electronic, secure, web-based case report form.

Primary outcome

The primary outcome was the recruitment rate into the trial defined as the proportion of eligible participants who were approached and recruited to the study over 12 months.

Secondary outcomes

The secondary outcomes were:
1. Performance of study procedures including retention of participants for the duration of the study, and feasibility of outcome recording and data collection systems.

2. Willingness of parents, children and surgeons to take part in a randomised study comparing operative versus non-operative treatment and identify anticipated recruitment rate. This was assessed from audio recorded family-surgeon recruitment consultations, interviews with patients, parents, surgeons and nurses, surgeon surveys and focus groups.

3. Clinical outcomes of trial treatment pathways including (i) safety and overall success of initial non-operative treatment (measured as the number of patients randomised to non-operative treatment, discharged from hospital without appendicectomy); (ii) complications of disease and treatment (measured during hospital stay and 6 month follow-up period); (iii) rate of recurrent appendicitis during 6 month follow-up period.

Blinding of treatment arm was not considered ethical or feasible, so treating staff, parents and participants were aware of treatment allocation. We aimed to determine the feasibility of a blinded discharge assessment and therefore blinded outcome assessment in a future RCT by attempting to complete a blinded discharge assessment for each participant. Once a decision to discharge the child had been made a member of the clinical team who has not been involved directly in the child’s treatment was asked to complete a discharge assessment. This assessor did not have prior knowledge of the randomisation or treatment received by the child. Upon completion of the discharge assessment, the assessor “guessed” which treatment the child received. If the assessor became unblinded during the assessment, this was recorded.

**Sample size and statistical analysis**

As a feasibility study, we did not specify a specific sample size but aimed to define our recruitment rate within an approximate 10% margin of error. Based on an anticipated study population available for recruitment of approximately 130 eligible participants across the three participating centres, we would be able to estimate a true 40% recruitment rate with a 95% confidence interval (CI) of 31% to 49% and a true 50% recruitment rate with a 95% CI of 41% to 59%. These numbers of participants in the feasibility RCT would be adequate to test treatment pathway procedures, data collection methods and loss to follow-up. Accordingly, the study duration was defined *a priori* as being 12 months.

Data analysis was performed by the study statistician who was blinded to treatment allocation by the use of coded data. As this is a feasibility study, all analyses were treated as preliminary and
exploratory, and data are reported descriptively. Feasibility outcomes (number of eligible patients, recruitment/retention rates, reasons for non-participation, success of blinding of the discharge assessor), treatment outcomes and complications are presented as simple summary statistics with 95% confidence intervals.

**Embedded qualitative study**

Full methods and outcomes of this have been published elsewhere. (3) The main aim of the qualitative study was to optimise trial recruitment on an iterative basis whilst the feasibility trial was still open to recruitment. Before recruitment commenced we delivered generic communication training, informed by trial communication literature, to recruiting health professionals at all three trial sites. We subsequently developed bespoke communication training informed by the ongoing thematic analysis of the qualitative data, which comprised recruitment consultations and interviews with families and staff. Training was delivered to sites at the end of month 4 of recruitment and again during month 9 of recruitment. The potential impact of the qualitative study was evaluated by determining recruitment rates across three phases of the study: ‘phase one’ being the first 4 months (March to June 2017), ‘phase two’ months 5-9 and ‘phase three’ as the final 3 months.

**Trial Governance**

A Study Management Group (SMG) was responsible for overseeing the day-to-day management of the trial. An independent Trial Steering Committee (TSC) and Data Monitoring and Safety Committee (DMSC) were convened to provide oversight of the study. Their roles and responsibilities which included adverse event monitoring were agreed at the beginning of the trial and documented in specific charters. Specific processes to report adverse events in a timely manner to the relevant committee were agreed.

The trial was carried out in accordance with a published protocol that was developed in accordance with the SPIRIT-C guidance, was registered prior to recruitment of the first participant (ISRCTN 15830435) and has been published previously. (7) The overall study was given ethical approval by the Hampshire A Research Ethics Committee (ref 16/SC/0596). The study is reported in accordance with the CONSORT 2010 statement (feasibility trial extension). (10)

**Changes to the study from the original protocol**

Following an analysis of follow-up rates during the study, we introduced an incentive to improve follow-up rates and improve ascertainment of follow-up data. This was introduced in March 2018 following a successful application to the ethics committee to make this amendment. All participants
who attended all remaining follow-up visits from that point onwards were offered a £10 voucher. The impact of this was assessed.

**Patient and public involvement**

The methodology for this feasibility trial was developed with a study specific advisory group comprising young people and parents, many of whom had experience of acute appendicitis. These were invited to join this group through existing regional young person’s advisory groups and through contacts of the clinical investigators. This group met prior to the start of the study and again regularly throughout its duration. The group oversaw all aspects of the trial that involved interaction with patients and families including all patient and family facing documentation (e.g. patient information sheets, consent forms, discharge information leaflets), the recruitment video, method and timing of initial approach for recruitment conversation and interview topic guides for the embedded qualitative research.

**Results**

All three centres opened to recruitment simultaneously on March 1st 2017 and were open to recruitment for 12 months until 28th February 2018. Final follow-up was completed on 31st August 2018. The trial profile is shown in Figure 2.

**Recruitment and participants**

Of 275 children screened, 131 fulfilled the eligibility criteria of whom 115 were approached about the study and of these 57 agreed to participate and were randomised. Thus the primary outcome (proportion of eligible patients who were approached and recruited) was 44% (95% CI 35-52), and recruitment rate of those approached was 50% (95% CI 40-59). Despite anticipated challenges in recruitment, participants were successfully recruited into the trial outside of normal working hours (40% were recruited between the hours of 6pm and 8am), recruitment rate per site across the whole study period ranged from 45% to 56% of those approached total of 21 different surgeons successfully recruited participants. Of 57 participants randomised, baseline characteristics were well matched (Error! Reference source not found.).

### Interventions received

Figure 2 shows participant flow through the clinical trial. Three participants withdrew consent for the study soon after randomisation. Reasons given for this were dissatisfaction with treatment allocated (n=2) and being too overwhelmed with the diagnosis to continue in the trial (n=1). The remaining 27 participants in the appendicectomy and 27 participants in the non-operative treatment arm both commenced the assigned intervention. All 27 participants in the appendicectomy received the allocated treatment whereas there was one protocol deviation in the non-operative treatment in a child whose parents withdrew consent for the study (but agreed to continued data collection) and requested appendicectomy eight hours after randomisation.

In the appendicectomy arm, all 27 children received the allocated intervention and were treated according to the clinical pathway. Histological diagnosis of the resected appendix revealed simple acute appendicitis in 17 (63%), perforated appendicitis in eight (30%), and a normal appendix in two (7%).

In the non-operative treatment arm, 19 of the 27 children (70%) responded successfully to non-operative treatment, followed the clinical pathway and were discharged from hospital. The remaining eight children underwent appendicectomy during their initial hospital admission. Reasons for appendicectomy were parental choice (withdrawal from treatment arm as described above) at 8 hours following randomisation (n=1), deterioration in clinical condition (according to protocol) at range 12 to 44 hours following randomisation (n=6), and no improvement after 48 hours of non-operative treatment (in accordance with protocol, n=1). In the children who deteriorated (n=6),
clinical reasons given included persistent fever and pain, worsening peritonism and worsening pain. In the one child who did not have any symptomatic improvement after 48 hours, the primary persisting complaint was that of ongoing severe abdominal pain. All these eight patients underwent successful appendicectomy during the initial hospital admission. Histological findings were uncomplicated acute appendicitis in four and perforated appendicitis in four.

**Discharge assessment and follow-up**

Thirty-four of 54 eligible children (63%) underwent a blinded discharge assessment. In the remaining 20, this was not possible due to non-availability of appropriate members of staff. In one case, the assessor was unblinded during the assessment. Following discharge, 26 of 54 (48%) participants (15 in the appendicectomy arm and 11 in the non-operative treatment arm) returned a diary card, the majority of which (n=23, 88%) were completed in full. One child was completely lost to follow-up and did not attend any follow-up appointment nor could be contacted by phone. This child was withdrawn from the study after the 3 month follow-up timepoint as they were known to have moved overseas. The remaining participants attended follow-up appointments or were contacted by phone at six weeks (n=48/54, 89% of those remaining in the study), three months (n= 46/54, 85%) and six months (n=45/53, 85%). All other participants either did not attend or did not respond to repeated requests for contact by telephone.

Part way through the study we introduced an incentive of a £10 shopping voucher to participants who completed all future follow-up assessments. Of the 3-month follow-up appointments, 47 were not incentivised and were completed by 39 participants (83%, 95% CI 72% to 93%), whereas seven were incentivised and all seven were completed (100%, 95% CI 59% to 100%). Of the 6-month follow-up appointments, 34 were not incentivised and were completed by 28 participants (83%, 95% CI 65% to 93%), and 19 were incentivised and were completed by 17 participants (89%, 95% CI 67% to 99%).

**Secondary outcomes**

There was no mortality in the six months following enrolment. During the six-month follow-up, seven children in the non-operative treatment arm developed recurrent appendicitis (24% of those randomised to non-operative treatment; 37% of the 19 who initially responded to non-operative treatment). Six of the seven underwent appendicectomy, with histological findings of simple acute appendicitis (n=4) and perforated appendicitis (n=2). The remaining participant presented with an appendix mass at the time of recurrence, which was successfully treated non-operatively and
subsequently underwent interval laparoscopic appendicectomy. At the final follow-up, 11 children initially randomised to receive non-operative treatment (41%) had not undergone appendicectomy. In the appendicectomy arm, three children (11%) were readmitted to hospital following initial treatment for treatment with intravenous antibiotics for fever and abdominal pain (n=1), or intra-abdominal fluid collection / abscess (n=2) including one child also treated with percutaneous drainage.

Adverse events during the 6-month follow-up are summarised in Table 2. In the appendicectomy arm, 22 adverse events were reported in 8 participants and in the non-operative treatment arm, 24 adverse events were reported in 15 participants. Of these, a small number were assigned as ‘possibly’ or ‘definitely’ attributed to the study intervention including: a rash at the time of receiving antibiotics (n=2), wound complications (dehiscence x1, infection x1, suture complications x1), and intra-abdominal fluid collections treated with drainage and antibiotics (n=1) or antibiotics alone(n=1).

Embedded qualitative study

The findings of the qualitative study are reported elsewhere.(3) These findings shaped the first bespoke training session at the end of month 4, which focussed on encouraging health professionals to use terminology that conveyed equipoise, exploring family treatment preferences and providing balancing information, and supported health professionals in responding to frequently asked questions from families. The second bespoke communication training session in month 9 (again informed by qualitative study findings) focused on ways that surgeons had improved their communication about CONTRACT since the first training, particularly with regard to equipoise. We also revisited examples of non-optimal communication, as well as ways to enhance explanations of randomisation, manage families’ expectations about scheduling of surgery if non-operative treatment failed, provide balanced communication of treatment risks, (i.e. discuss risks relating to both treatment arms) and respond to families’ further questions (see full report(3)). Recruitment rate increased following each of these bespoke training sessions from 38% during the initial 4 months to 47% in months 5-9 and to 72% in months 10-12. Final recommendations from the qualitative study to inform the design of a future definitive trial, and paediatric urgent care surgical trials more broadly, are summarised in Box 1.

Discussion

To our knowledge this is the first study to determine the feasibility of recruiting children with uncomplicated acute appendicitis to a RCT comparing appendicectomy with a non-operative treatment pathway. By recruiting to this feasibility RCT we have clearly demonstrated that it is
possible to identify and recruit children with uncomplicated acute appendicitis even outside of normal working hours (an important consideration since children with appendicitis frequently present at night and at the weekend). We achieved this by integrating the research protocol with clinical teams. They approached children and families at the time of an emergency admission, discussed the trial with them and recruited when possible. Paediatric surgeons were willing to follow the trial interventions, and the trial pathways and follow-up were found to be acceptable to patients and families. Through our qualitative work we have identified training requirements of these clinical teams and developed trial specific training packages to optimise communication and recruitment. We have ascertained data regarding follow-up rates and how to optimise data collection that will inform trial design. Overall our findings support proceeding to a full definitive RCT to determine the comparative effectiveness of appendicectomy and non-operative treatment.

The main strength of this study is that we have established feasibility by recruiting to a feasibility RCT rather than using survey or qualitative work alone to predict feasibility. We therefore have secure knowledge that a future RCT is feasible in the very settings in which we intend it to be performed. A further strength is that we demonstrated this feasibility in three geographically distinct UK centres that serve populations with differing socioeconomic profiles, and with 3 different groups of surgeons. Additionally we embedded qualitative methodology to develop bespoke training for recruiting teams and implemented this to optimise communication and recruitment within the study. The principal limitation of this study is that we have conducted the work only in 3 centres and these may not be representative of future sites. However, work we have completed alongside this feasibility trial with other centres suggest there is adequate interest to proceed with a larger trial. We will need to ensure adequate support and training for clinical and research teams at new sites for our future RCT.

In keeping with other previous studies that have evaluated recruitment of children to research studies including RCTs in urgent care settings, we found that parental uptake was acceptably high to make a future trial feasible. (12, 13) To our knowledge this is the first time such a feasibility RCT has been performed in the setting of acute appendicitis in children and our findings likely have implications for the design and delivery of other urgent care trials in children even where trial interventions are complex. Our work provides evidence for child health researchers contemplating ‘hard to do’ trials where potentially eligible children often attend out of normal hours, that such trials are feasible and acceptable particularly with iterative training for recruiters. Through this feasibility trial we are able for the first time to report on the safety of non-operative treatment for uncomplicated acute appendicitis in the United Kingdom. This is an important aspect given the lack of familiarity with this treatment approach amongst most UK surgeons, and further supports.
proceeding to a larger RCT. Whilst we acknowledge an assessment of safety of non-operative treatment based on the relatively small numbers here should be made with caution, our findings that there is no evidence of harm are in keeping with a growing body of literature suggesting that non-operative treatment is indeed a safe treatment approach (2, 14). This finding is also timely, because more recently there has been a dramatic uptake of non-operative treatment for appendicitis during the SARS-CoV-2 pandemic in both adults and children (15, 16). Whilst there are several similar ongoing trials comparing non-operative treatment with appendicectomy for children with uncomplicated acute appendicitis,(17, 18) none are recruiting in the UK. We continue to believe that a UK trial is important to understand the comparative effectiveness of these two very different treatments and the comparative cost-effectiveness within the NHS. Given the increase in use of non-operative treatment associated with the SARS-CoV-2 pandemic (16), understanding the outcomes of these different treatment approaches is arguably now more important than ever.

The clinical features and outcomes of participants in this feasibility RCT are not the focus of this report but some aspects are worthy of discussion in relation to feasibility of a future trial. Baseline characteristics of trial participants is as anticipated from the existing literature of children with acute appendicitis suggesting we have enrolled a representative population (8, 19). Despite our efforts to only enrol children with uncomplicated appendicitis, 30% of children allocated to receive appendicectomy had perforated appendicitis. Our experience suggests differentiating between uncomplicated and complicated disease based on clinical judgement by a paediatric surgeon is inadequate both for a future RCT as well as future clinical practice. Related to this is that we suspect the relatively low success rate of non-operative treatment reported here when compared to other studies (2) is likely due to recruitment of children with more advanced appendicitis than had been intended. For a future trial to be acceptable to all stakeholders therefore, it will be necessary to exclude those children with complicated appendicitis more reliably. Some similar studies have used ultrasound to make an assessment of severity of appendicitis and thereby eligibility (17, 20, 21). Whilst seemingly attractive, the reliability of ultrasound is not 100% for this purpose and more importantly ultrasound is not routinely used for diagnostic purposes in the UK. In this trial just 28% of participants received an ultrasound and in a recent large UK observational study just 40% of children presenting with abdominal pain had an ultrasound (8). Any trial protocol that demanded ultrasound to assess eligibility would limit the trial generalisability, limit the number available for recruitment and would not be representative of current UK practice. Instead we intend to use a bespoke validated scoring system based on clinical and laboratory parameters; work is underway to develop this.
In conclusion, these data show that it is feasible to recruit children with uncomplicated acute appendicitis to a RCT comparing appendicectomy with non-operative treatment. There is no evidence for a poor safety profile of non-operative management. The comparative effectiveness of appendicectomy and non-operative treatment of uncomplicated acute appendicitis remains an important research question. The next step is to complete a definitive RCT with inclusion criteria modified in order to prevent recruitment of children with perforated appendicitis and this feasibility trial has been crucial in refining the design and implementation of that study.

What is already known on this topic
- Non-operative treatment is an alternative to appendicectomy for children with uncomplicated acute appendicitis but the comparative effectiveness of these treatments is not known.
- A randomised trial comparing these treatments will be challenging due to the urgent care setting, complex treatments interventions and patient and surgeon preferences.
- Feasibility studies can help establish the feasibility of future RCTs and enhance their design to optimise chances of success and minimise waste of resources

What this study adds
- A future RCT comparing the effectiveness and cost-effectiveness of non-operative treatment with appendicectomy for children with uncomplicated acute appendicitis is feasible
• Supported by embedded qualitative research to inform communication and recruiter training we have identified opportunities to improve design and implementation of the future RCT

• Hard to do trials where potentially eligible children often attend at night are feasible and acceptable particularly with iterative training for recruiters

STUDY SCHEMA

- Inclusion criteria met
- Study explained, informed consent
- Randomisation

**Appendectomy**
- NBW, broad spectrum antibiotics
- Clinical deterioration
- Stable/Improved
- Review at 24 hours following randomisation
- Clinical deterioration
- No improvement
- Improvement
- Continue non-operative treatment
- Continue non-operative treatment
- Clinical deterioration?

**Non-operative treatment**
- NBW, broad spectrum antibiotics, regular clinical review
- Stable/Improved
- Review at 48 hours following randomisation
- Clinical deterioration
- No improvement
- Improvement
- Continue non-operative treatment
- Continue non-operative treatment

Proceed to appendectomy

Post-operative antibiotics per institutional guidelines

Guidance:
- Normal appendicitis or non-perforated appendicitis - no further antibiotics
- Perforated appendicitis* - minimum 3 days IV antibiotics

Assess for discharge**

NBW = nil by mouth

* non-operative treatment - NBW to ap for initial 12h minimum then advance diet as tolerated; IV antibiotics 24h minimum, change to oral once sterile for 24h, total course 10 days; analgesia

* appendicitis group - no routine use of nasogastric tube or urinary catheter, advanced diet as tolerated

* defined as either seeing a hole in the appendix on faecal matter/feacolith in the peritoneal cavity

** criteria for discharge include: vital signs within normal limits, tolerating light diet, adequate oral analgesia, mobile
Figure 2. CONSORT diagram of CONTRACT feasibility RCT
Box 1 Recommendations to optimise informed consent, recruitment and retention in future paediatric urgent care surgical trials.

1. Involve children and young people in research discussions and decision-making where possible, as per current guidance (1), whilst being sensitive to parents’ anxieties about what their children hear regarding treatment complications.

2. Provide families with advance information about how a child’s treatment will be managed pre-randomisation and in both treatment arms. Where relevant, this should include the timing of trial treatments and the timeframe in which families should expect to see an improvement in their child’s conditions.

3. Parents may link treatment delays to the additional procedures required for the trial and this could discourage them from participating, or remaining, in the trial. Where possible, delays in delivering treatments pre and post-randomisation should be minimised.

4. In cases where children and parents differ in their treatment preferences, randomisation may offer a means of resolving this conflict. Sensitively explain treatment arm allocation to trial participants. If a child is upset with their allocation, further exploring their treatment preference may help to allay their concerns.

5. Time to decide: develop a strategy to allow families to indicate when they have made a decision regarding participation, so minimising delays from the perspective of families.

6. Consider staffing strategies to support health professionals in recruiting families outside of normal working hours.

7. Be aware of family sensitivities when explaining post-surgery findings in the context of a trial.

* Note that AEs that were reported as serious (SAEs) during the early months of the trial are included here as reported on the basis of standardised reporting terminology in RCTs in that they resulted in either prolongation of hospital stay, readmission to hospital, or death. However since these were all predictable and related more to the disease process rather than the study interventions, we subsequently reclassified these ‘expected’ SAEs as AEs in protocol amendment 1 April 10th 2017. Thus although similar AEs did occur beyond the first 2 months of the study, they were no longer reported as SAEs.
