Background
Chronic suppurative otitis media (CSOM), sometimes referred to as chronic otitis media (COM), is a chronic inflammation and often polymicrobial infection (involving more than one micro-organism) of the middle ear and mastoid cavity, characterised by ear discharge (otorrhoea) through a perforated tympanic membrane. The predominant symptoms of CSOM are ear discharge and hearing loss. Antibiotics are the most common treatment for CSOM, which act to kill or inhibit the growth of micro-organisms that may be responsible for the infection. Antibiotics can be administered both topically and systemically, and can be used alone or in addition to other treatments for CSOM such as ear cleaning (aural toileting).

Objectives
To assess the effects of topical versus systemic antibiotics for people with CSOM.

Search methods
The Cochrane ENT Information Specialist searched the Cochrane ENT Register; Central Register of Controlled Trials (CENTRAL via the Cochrane Register of Studies); Ovid MEDLINE; Ovid Embase; CINAHL; Web of Science; ClinicalTrials.gov; ICTR and additional sources for published and unpublished trials. The date of the search was 16 March 2020.

Selection criteria
We included randomised controlled trials (RCTs) with at least a one-week follow-up involving patients (adults and children) who had chronic ear discharge of unknown cause or CSOM, where the ear discharge had continued for more than two weeks.

The studies compared topical antibiotics against systemic (oral, injection) antibiotics. We separated studies according to whether they compared the same type of antibiotic in both treatment groups, or different types of antibiotics. For each comparison we considered whether there was background treatment for both treatment groups, for example aural toileting (ear cleaning).

Data collection and analysis
We used the standard Cochrane methodological procedures. We used GRADE to assess the certainty of the evidence for each outcome.
Our primary outcomes were: resolution of ear discharge or ‘dry ear’ (whether otoscopically confirmed or not, measured at between one week and up to two weeks, two weeks up to four weeks, and after four weeks), health-related quality of life using a validated instrument, ear pain (otalgia) or discomfort or local irritation. Secondary outcomes included hearing, serious complications and ototoxicity measured in several ways.

Main results
Six studies (445 participants), all with high risk of bias, were included. All but two studies included patients with confirmed CSOM, where perforation of the ear drum was clearly documented. None of the studies reported results for resolution of ear discharge after four weeks or health-related quality of life.

1. Topical versus systemic administration of the same type of antibiotics (quinolones)
Four studies (325 participants) compared topical versus systemic (oral) administration of ciprofloxacin. Three studies reported resolution of ear discharge at one to two weeks and found that the topical administration may slightly increase resolution (risk ratio (RR) 1.48, 95% confidence interval (CI) 1.24 to 1.76; 285 participants; 3 studies; I² = 0%; low-certainty evidence). In these studies, aural toileting was either not mentioned, or limited to the first visit.

Three studies (265 participants) reported that they did not suspect ototoxicity in any participants, but it is unclear how this was measured (very low-certainty evidence). No studies reported the outcomes of ear pain or serious complications. No studies reported results for hearing, despite it being measured in three studies.

2. Topical versus systemic administration of different types of antibiotics (quinolones versus aminoglycosides)
One study (60 participants) compared topical ciprofloxacin versus gentamicin injected intramuscularly. No aural toileting was reported. Resolution of ear discharge was not measured at one to two weeks. The study did not report any ‘side effects’ from which we assumed that no ear pain, suspected ototoxicity or serious complications occurred (very low-certainty evidence). The study stated that "no worsening of the audiometric function related to local or parenteral therapy was observed".

3. Topical versus systemic administration of different types of antibiotics (quinolones versus amoxicillin-clavulanic acid)
One study compared topical ofloxacin with amoxicillin-clavulanic acid with all participants receiving suction ear cleaning at the first visit. It is uncertain if there is a difference between the two groups in resolution of ear discharge at one to two weeks due to study limitations and the very small sample size (RR 2.93, 95% CI 1.50 to 5.72; 56 participants; very low-certainty evidence). It is unclear if there is a difference between topical quinolone compared with oral amoxicillin-clavulanic acid with regards to ear pain, hearing or suspected ototoxicity (very low-certainty evidence). No studies reported the outcome of serious complications.

Authors' conclusions
There was a limited amount of low-quality evidence available, from studies completed over 15 years ago, to examine whether topical or systemic antibiotics are more effective in achieving resolution of ear discharge for people with CSOM. However, amongst this uncertainty there is some evidence to suggest that the topical administration of antibiotics may be more effective than systemic administration of antibiotics in achieving resolution of ear discharge (dry ear). There is limited evidence available regarding different types of antibiotics. It is not possible to determine with any certainty whether or not topical quinolones are better or worse than systemic aminoglycosides.

These two groups of compounds have different adverse effect profiles, but there is insufficient evidence from the included studies to make any comment about these. In general, adverse effects were poorly reported.

PLAIN LANGUAGE SUMMARY
Local antibiotics or antibiotics that target the whole body: which works better to treat chronic suppurative otitis media (persistent or recurring ear infection with discharge)?

Why is this question important?
Chronic suppurative otitis media (CSOM), also known as chronic otitis media (COM), is an inflammation and infection of the middle ear that lasts for two weeks or more. People with CSOM usually experience recurrent or persistent discharge – fluid that leaks out from a hole or tear in the eardrum – and hearing loss.

Antibiotics (medicines that fight bacterial infections) are the most common treatment for CSOM. Antibiotics can:
- be applied to part of the body (locally) in the form of drops, sprays, ointments or creams (topical antibiotics); or
- treat the whole body (systemic antibiotics) when injected, or taken orally (by mouth).

To find out whether topical or systemic antibiotics are better for treating CSOM, and whether they have different adverse (unwanted) effects, we reviewed the evidence from research studies.
How did we identify and evaluate the evidence?

First, we searched the medical literature for studies that followed adults or children with CSOM for at least one week and compared:

- the topical and systemic forms of the same antibiotic; or
- a topical antibiotic against a different, systemic antibiotic.

We then compared the results and summarised the evidence from all the studies. Finally, we rated our confidence in the evidence, based on factors such as study methods and sizes, and the consistency of findings across studies.

What did we find?

We found six studies that involved a total of 445 people. People were treated with antibiotics for between five days and two weeks, and were followed for up to 21 days. Studies were conducted in Spain (three studies), Italy (two studies) and Hong Kong (one study). Three studies provided information about how they were funded or who supplied medicines: one study received funding from a university, and medicines were provided by pharmaceutical companies in two studies.

Studies compared:

- quinolone ear drops against oral quinolone (four studies);
- quinolone ear drops against injected aminoglycosides (one study);
- ofloxacin ear drops against oral amoxicillin-clavulanic acid (one study).

Quinolone ear drops compared to quinolone taken orally

Compared to oral quinolone, quinolone ear drops may slightly increase the chances of ear discharge resolving after one to two weeks. We do not know if there is a difference between the two treatments for:

- hearing;
- ear pain;
- serious complications such as facial palsy (weakness of the muscles in the face);
- meningitis (an inflammation of fluid and membranes in the brain); or
- ototoxicity (when a person develops hearing or balance problems due to a medicine).

This is because either no studies reported information about these effects, or we have too little confidence in the evidence available.

Quinolone ear drops compared to injected aminoglycosides

We do not know if quinolone ear drops are better or worse than injected aminoglycosides for treating CSOM. Only one study investigated this and it provided insufficient robust evidence.

Ofloxacin ear drops against oral amoxicillin-clavulanic acid

We do not know if ofloxacin ear drops are better or worse than oral amoxicillin-clavulanic acid for treating CSOM. Only one study investigated this and it provided insufficient robust evidence.

No study reported information about the effects of different treatments on ear discharge after four weeks or health-related quality of life.

What does this mean?

Topical antibiotics may be more effective than systemic antibiotics at resolving ear discharge. We do not know whether systemic or topical antibiotics are better for improving hearing. We need more evidence from robust studies to be able to compare the effects of topical and systemic antibiotics on aspects such as health-related quality of life or ear pain. We also need more information about adverse effects.

How up-to-date is this review?

The evidence in this Cochrane Review is current to March 2020.
### Summary of findings 1. Topical quinolone compared to oral quinolone for chronic suppurative otitis media

#### Topical quinolone compared to oral quinolone for chronic suppurative otitis media

**Patient population:** people (of any age) with CSOM  
**Setting:** various; general hospital in Spain (de Miguel 1999; Povedano 1995), three tertiary hospitals in Spain (Ramos 2003) and university clinic in Italy (Esposito 1990)  
**Intervention:** topical quinolone  
**Comparison:** oral quinolone

1. Downgraded by one level for risk of bias (study limitations) as there was no blinding of participants (although outcome assessors were blinded).
2. Downgraded by two levels for imprecision as there was only one study with a very small sample size (56 participants).
3. Downgraded by two levels due to imprecision as this was a single study with only 56 participants and the data were only reported narratively.
BACKGROUND

This is one of a suite of Cochrane Reviews evaluating the comparative effectiveness of non-surgical interventions for CSOM using topical antibiotics, topical antibiotics with corticosteroids, systemic antibiotics, topical antiseptics and aural toileting (ear cleaning) methods (Table 1).

This review compares the effectiveness of topical antibiotics (without corticosteroids) against systemic antibiotics for CSOM.

Description of the condition

Chronic suppurative otitis media (CSOM), which is also often referred to as chronic otitis media (COM), is a chronic inflammation and infection of the middle ear and mastoid cavity, characterised by ear discharge (otorrhoea) through a perforated tympanic membrane.

The predominant symptoms of CSOM are ear discharge and hearing loss. Ear discharge can be persistent or intermittent, and many sufferers find it socially embarrassing (Orji 2013). Some patients also experience discomfort or earache. Most patients with CSOM experience temporary or permanent hearing loss with average hearing levels typically between 10 and 40 decibels (Jensen 2013). The hearing loss can be disabling, and it can have an impact on speech and language skills, employment prospects, and on children’s psychosocial and cognitive development, including academic performance (Ellemraid 2010; Olatoke 2008; WHO 2004). Consequently, quality of life can be affected. CSOM can also progress to serious complications in rare cases (and more often when cholesteatoma is present): both extracranial complications (such as mastoid abscess, postauricular fistula and facial palsy) and intracranial complications (such as otitic meningitis, lateral sinus thrombosis and cerebellar abscess) have been reported (Dubey 2007; Yorgancilar 2013).

CSOM is estimated to have a global incidence of 31 million episodes per year, or 4.8 new episodes per 1000 people (all ages), with 22% of cases affecting children under five years of age (Monasta 2012; Schilder 2016). The prevalence of CSOM varies widely between countries, but it disproportionately affects people at socio-economic disadvantage. It is rare in high-income countries, but common in many low- and middle-income countries (Mahadevan 2012; Monasta 2012; Schilder 2016; WHO 2004).

Definition of disease

There is no universally accepted definition of CSOM. Some define CSOM in patients with a duration of otorrhoea of more than two weeks but others may consider this an insufficient duration, preferring a minimum duration of six weeks or more than three months (Verhoeff 2006). Some include diseases of the tympanic membrane within the definition of CSOM, such as tympanic perforation without a history of recent ear discharge, or the disease cholesteatoma (a growth of the squamous epithelium of the tympanic membrane).

In accordance with a consensus statement, here we use CSOM only to refer to tympanic membrane perforation, with intermittent or continuous ear discharge (Gates 2002). We have used a duration of otorrhoea of two weeks as an inclusion criterion, in accordance with the definition used by the World Health Organization, but we have used subgroup analyses to explore whether this is a factor that affects observed treatment effectiveness (WHO 2004).

Many people affected by CSOM do not have good access to modern primary healthcare, let alone specialised ear and hearing care, and in such settings health workers may be unable to view the tympanic membrane to definitively diagnose CSOM. It can also be difficult to view the tympanic membrane when the ear discharge is profuse. Therefore we have also included, as a subset for analysis, studies where participants have had chronic ear discharge for at least two weeks, but where the diagnosis is unknown.

At-risk populations

Some populations are considered to be at high risk of CSOM. There is a high prevalence of disease among Indigenous people such as the Aboriginal and Torres Strait Islander Australian, Native American and Inuit populations. This is likely due to an interplay of factors, including socio-economic deprivation and possibly differences resulting from population genetics (Bhutta 2016). Those with primary or secondary immunodeficiency are also susceptible to CSOM. Children with craniofacial malformation (including cleft palate) or chromosomal mutations such as Down syndrome are prone to chronic non-suppurative otitis media (‘glue ear’), and by extrapolation may also be at greater risk of suppurrative otitis media. The reasons for this association with craniofacial malformation are not well understood, but may include altered function of the Eustachian tube, coexistent immunodeficiency, or both. These populations may be less responsive to treatment and more likely to develop CSOM, recurrence or complications.

Children who have a grommet (ventilation tube) in the tympanic membrane to treat glue ear or recurrent acute otitis media may be more prone to develop CSOM; however, their pathway to CSOM may differ and therefore they may respond differently to treatment. Children with grommets who have chronic ear discharge meeting the CSOM criteria are therefore considered to be a separate high-risk subgroup (van der Veen 2006).

Treatment

Treatments for CSOM may include topical antibiotics (administered into the ear) with or without steroids, systemic antibiotics (given either by mouth or by injection), topical antiseptics and ear cleaning (aural toileting), all of which can be used on their own or in various combinations. Whereas primary healthcare workers or patients themselves can deliver some treatments (for example, some aural toileting and antiseptic washouts), in most countries antibiotic therapy requires prescription by a doctor. Surgical interventions are an option in cases where complications arise or in patients who have not responded to pharmacological treatment; however, there is a range of practice in terms of the type of surgical intervention that should be considered and the timing of the intervention. In addition, access to or availability of surgical interventions is setting-dependent. This series of Cochrane Reviews therefore focuses on non-surgical interventions. In addition, most clinicians consider cholesteatoma to be a variant of CSOM, but acknowledge that it will not respond to non-surgical treatment (or will only respond temporarily) (Bhutta 2011). Therefore, studies in which more than half of the participants were identified as having cholesteatoma are not included in these reviews.
Description of the intervention

Antibiotics are the most commonly used treatment for CSOM. They can be administered topically (as drops, ointments, sprays or creams to the affected area) or systemically (either by mouth or by injection into a vein (intravenous) or muscle (intramuscular)).

Topical application has the advantage of potentially delivering high concentrations of antibiotic to the affected area, whereas systemic antibiotics are absorbed and distributed throughout the body. However, the penetration of topical antibiotics into the middle ear may be compromised if the perforation in the tympanic membrane is small or there is copious mucopurulent discharge in the ear canal that cannot be cleaned. It may also be difficult to achieve compliance with topical dosing in young children. In these cases, systemic antibiotics may have an advantage.

How the intervention might work

CSOM is a chronic and often polymicrobial (involving more than one micro-organism) infection of the middle ear. Broad-spectrum antibiotics such as second-generation quinolones and aminoglycosides, which are often active against the most frequently cultured micro-organisms (Pseudomonas aeruginosa and Staphylococcus aureus), are therefore commonly used (Mittal 2015) (Table 2). It is possible that antibiotics for CSOM that target Pseudomonas aeruginosa may have an advantage over antibiotics that do not. Dose and duration of treatment are also important factors, but are less likely to affect relative effectiveness if given within the therapeutic range. Generally, it is necessary to administer treatment for at least five days, and a duration of one to two weeks is sufficient to resolve uncomplicated infections. However, in some cases it may take more than two weeks for the ear to become dry and therefore longer follow-up (more than four weeks) may be needed to monitor for recurrence of discharge.

Some antibiotics (such as aminoglycosides) can be toxic to the inner ear (ototoxicity), which might be experienced as sensorineural hearing loss, dizziness or tinnitus, but this is less likely to be a risk when applied topically in patients with CSOM (Phillips 2007). Clinically relevant ototoxicity or vestibulotoxicity (damage to the vestibular system) from topical aminoglycosides in the treatment of CSOM is likely to be rare. However, expert opinion on the use of potentially ototoxic antibiotics varies by country; some countries do not recommend their use or may limit the use of topical aminoglycosides, others do not specifically limit their use and others may provide guidance on their use (Gilbert 2007).

Local discomfort, ear pain or itching may occur through the action of putting ear drops into the ear or because the topical antibiotics or their excipients cause chemical or allergic irritation of the skin of the outer ear.

Systemic antibiotics can have off-target side effects, such as diarrhoea or nausea. However, the risk or incidence of these events is not expected to be different from treatment of other common infections since the doses and duration of treatment used are similar in CSOM. A broader concern is the association of the overuse of antibiotics with increasing resistance among community- and hospital-acquired pathogens.

Why it is important to do this review

Although topical antibiotics are widely recommended as a first-line treatment for CSOM, systemic antibiotics are still used in situations where the delivery of drops to the middle ear is difficult. These include the treatment of young children and people with small perforations and/or copious ear discharge. Some antibiotics may be unsuitable for formulation as a topical ear drop so systemic antibiotics remain a viable option for the delivery of broad-spectrum antibiotics. In some regions and countries topical antibiotic drops are less available than systemic antibiotics. Evidence-based knowledge of the relative effectiveness of the different routes of administration of antibiotics could help to optimise their use.

OBJECTIVES

To assess the effects of topical versus systemic antibiotics for people with chronic suppurative otitis media (CSOM).

METHODS

Criteria for considering studies for this review

Types of studies

We included studies with the following design characteristics:

- Randomised controlled trials (including cluster-randomised trials where the unit of randomisation is the setting or operator) and quasi-randomised trials.
- Patients were followed up for at least one week.

We excluded studies with the following design characteristics:

- Cross-over trials, because CSOM is not expected to be a stable chronic condition. Unless data from the first phase were available, we excluded such studies.
- Studies that randomised participants by ear (within-patient controlled) because by definition the effects of systemic interventions are not localised.

Types of participants

We included studies with patients (adults and children) who had:

- chronic ear discharge of unknown cause; or
- chronic suppurative otitis media.

We defined patients with chronic ear discharge as patients with at least two weeks of ear discharge, where the cause of the discharge was unknown.

We defined patients with chronic suppurative otitis media (CSOM) as patients with:

- chronic or persistent ear discharge for at least two weeks; and
- a perforated tympanic membrane.

We did not exclude any populations based on age, risk factors (cleft palate, Down syndrome), ethnicity (e.g. Australian Aboriginal or Torres Strait Islanders) or the presence of ventilation tubes (grommets). Where available, we recorded these factors in the patient characteristics section during data extraction from the studies. If any of the included studies recruited these patients as
majority (80% or more), we analysed them in a subgroup analysis (see Subgroup analysis and investigation of heterogeneity).

We excluded studies where the majority (more than 50%) of participants:

- had an alternative diagnosis to CSOM (e.g. otitis externa);
- had underlying cholesteatoma;
- had ear surgery within the last six weeks.

We did not include studies designed to evaluate interventions in the immediate peri-surgical period, which were focused on assessing the impact of the intervention on the surgical procedure or outcomes.

**Types of interventions**

**Intervention**

We included all topical and systemic antibiotics. Topical antibiotics are applied directly into the ear canal. The most common formulations are ear drops but we have also included other formulations such as sprays. Systemic antibiotics are administered orally or parenterally (intramuscular or intravenous).

We excluded studies that selected an antibiotic based upon results of a microbial culture and antibiotic sensitivity testing of the ear discharge.

**Duration**

At least five days of treatment with antibiotics was required, except for antibiotics where a shorter duration has been proven to be equivalent (e.g. azithromycin for systemic antibiotics).

**Dose**

For topical antibiotics there was no limitation on the dose, concentration, volume or frequency of application.

For systemic antibiotics there was no limitation on the dose or frequency of administration.

**Comparisons**

The following were the comparators:

- The same antibiotic administered systemically (topical antibiotic A versus systemic antibiotic A),
- A different antibiotic administered systemically (topical antibiotic A versus systemic antibiotic B).

We planned to analyse three main scenarios depending on which common therapy was applied in the background:

- **Topical versus systemic antibiotics as a single treatment (main therapy):** this included studies where all participants in both treatment groups either received no other treatment or only received aural toileting. This has also included situations where antiseptics were applied only once (e.g. as part of microsuction at the start of treatment).
- **Topical versus systemic antibiotics as an add-on therapy to antiseptics:** this included studies where all participants in both treatment groups also used a daily antiseptic, with or without aural toileting.
- **Topical versus systemic antibiotics as an add-on therapy to other systemic or topical antibiotics:** this included studies where all participants (in the intervention and comparator groups) received antibiotics as a background therapy - this may have been topical or systemic antibiotics, but was identical for both groups. Participants in the two groups were then randomised to receive either topical or systemic antibiotics in addition to the background treatment.

Many comparison pairs were possible in this review. The main comparisons of interest that we have summarised and presented in the 'Summary of findings' table were:

- topical antibiotic versus the same antibiotic administered systemically;
- topical antibiotic versus a different antibiotic administered systemically; and
- topical antibiotic versus the same antibiotic administered systemically, where topical antiseptics were used in both arms.

**Types of outcome measures**

We analysed the following outcomes in the review, but we did not use them as a basis for including or excluding studies.

We extracted and reported data from the longest available follow-up for all outcomes.

**Primary outcomes**

- Resolution of ear discharge or 'dry ear' (whether otoscopically confirmed or not), measured at:
  - between one week and up to two weeks;
  - two weeks to up to four weeks; and
  - after four weeks.
- Health-related quality of life using a validated instrument for CSOM (e.g. Chronic Otitis Media Questionnaire (COMQ)-12 (Phillips 2014a; Phillips 2014b; van Dinh 2015), Chronic Otitis Media Outcome Test (COMOT)-15 (Baumann 2011), Chronic Ear Survey (CES) (Nadol 2000)).
- Ear pain (otalgia) or discomfort or local irritation.

**Secondary outcomes**

- Hearing, measured as the pure-tone average of air conduction thresholds across four frequencies tested (500 Hz, 1000 Hz, 2000 Hz and 4000 Hz) of the affected ear. If this was not available, we reported the pure-tone average of the thresholds measured.
- Serious complications, including intracranial complications (such as otitic meningitis, lateral sinus thrombosis and brain abscess) and extracranial complications (such as mastoid abscess, postauricular fistula and facial palsy), and death.
- Ototoxicity; this was measured as 'suspected ototoxicity' as reported by the studies where available, and as the number of people with the following symptoms that may be suggestive of ototoxicity:
  - sensorineural hearing loss;
  - balance problems/dizziness/vertigo;
  - tinnitus.
Search methods for identification of studies

The Cochrane ENT Information Specialist conducted systematic searches for randomised controlled trials and controlled clinical trials. There were no language, publication year or publication status restrictions. The date of the search was 16 March 2020.

Electronic searches

The Information Specialist searched:

- the Cochrane ENT Register (searched via the Cochrane Register of Studies to 16 March 2020);
- the Cochrane Central Register of Controlled Trials (CENTRAL) (searched via the Cochrane Register of Studies Web to 16 March 2020);
- Ovid MEDLINE(R) Epub Ahead of Print, In-Process & Other Non-Indexed Citations, Ovid MEDLINE(R) Daily and Ovid MEDLINE(R) (1946 to 16 March 2020);
- Ovid EMBASE (1974 to 16 March 2020);
- EBSCO CINAHL (1982 to 16 March 2020);
- LILACS (Latin American and Caribbean Health Science Information database), lilacs.bvsalud.org (search to 16 March 2020);
- Web of Knowledge, Web of Science (1945 to 16 March 2020);
- ClinicalTrials.gov, www.clinicaltrials.gov (search via the Cochrane Register of Studies to 16 March 2020);
- World Health Organization (WHO) International Clinical Trials Registry Platform (ICTRP) (search to 16 March 2020).

We also searched:

- IndMed (search to 22 March 2018);
- African Index Medicus (search to 22 March 2018).

The search strategies for major databases are detailed in Appendix 1. The Information Specialist modelled subject strategies for databases on the search strategy designed for CENTRAL. The strategies were designed to identify all relevant studies for a suite of reviews on various interventions for chronic suppurrative otitis media (Bhutta 2020; Brennan-Jones 2020a; Brennan-Jones 2020b; Chong 2021; Chong 2018b; Heaad 2020a; Head 2020b). Where appropriate, they were combined with subject strategy adaptations of the highly sensitive search strategy designed by Cochrane for identifying randomised controlled trials and controlled clinical trials (as described in the Cochrane Handbook for Systematic Reviews of Interventions Version 5.1.0, Box 6.4.b. (Handbook 2011).

Searching other resources

We scanned the reference lists of identified publications for additional trials and contacted trial authors where necessary. In addition, the Information Specialist searched Ovid MEDLINE to retrieve existing systematic reviews relevant to this systematic review, so that we could scan their reference lists for additional trials. The Information Specialist also ran non-systematic searches of Google Scholar to retrieve grey literature and other sources of potential trials.

We did not perform a separate search for adverse effects. We considered adverse effects described in included studies only.

We contacted original authors for clarification and further data if trial reports were unclear and we arranged translations of papers where necessary.

Data collection and analysis

Selection of studies

At least two review authors (KH/LYC) independently screened all titles and abstracts of the references obtained from the database searches to identify potentially relevant studies. At least two review authors (KH/LYC) evaluated the full text of each potentially relevant study to determine whether it met the inclusion and exclusion criteria for this review.

We resolved any differences by discussion and consensus, with the involvement of a third author for clinical and methodological input where necessary.

Data extraction and management

At least two review authors (KH/LYC/CBJ/MB) independently extracted data from each study using a standardised data collection form (see Appendix 2). Whenever a study had more than one publication, we retrieved all publications to ensure complete extraction of data. Where there were discrepancies in the data extracted by different review authors, we checked these against the original reports and resolved any differences by discussion and consensus, with the involvement of a third author or a methodologist where appropriate. We contacted the original study authors for clarification or for missing data whenever possible. If differences were found between multiple publications of a study, we contacted the original authors for clarification. We used data from the main paper(s) if no further information was found.

We included key characteristics of the included studies, such as study design, setting (including location), year of study, sample size, age and sex of participants, and how outcomes were defined or collected in the studies. In addition, we collected baseline information on prognostic factors or effect modifiers (see Appendix 2). For this review, this included the following information whenever available:

- duration of ear discharge at entry to the study;
- diagnosis of ear discharge (where known);
- number of people who may have been at higher risk of CSOM, including those with cleft palate or Down syndrome;
- ethnicity of participants including the number who were from Indigenous populations;
- number who had previously had ventilation tubes (grommets) inserted (and, where known, the number who had tubes still in place);
- number who had previous ear surgery;
- number who had previous treatments for CSOM (non-responders, recurrent versus new cases).

We recorded concurrent treatments alongside the details of the interventions used. See the 'Data extraction form' in Appendix 2 for more details.

For the outcomes of interest to the review, we extracted the findings of studies on an available case analysis basis, i.e. we included all available data from patients at the time points specified, and
irrespective of whether patients had complied with or received the treatment as planned.

In addition to extracting pre-specified information about study characteristics and aspects of methodology relevant to risk of bias, we extracted the following summary statistics for each trial and each outcome:

- For continuous data: the mean values, standard deviations and number of patients for each treatment group. Where endpoint data were not available, we extracted the values for change from baseline. We analysed data from disease-specific quality of life scales such as COMQ-12, COMOT-15 and CES as continuous data.
- For binary data: the number of participants who experienced an event and the number of patients assessed at the time point.
- For ordinal scale data: if the data appeared to be approximately normally distributed or if the analysis that the investigators performed suggested parametric tests were appropriate, then we treated the outcome measures as continuous data. Alternatively, if data were available, we converted it into binary data.
- Time-to-event outcomes: we did not expect any outcomes to be measured as time-to-event data. However, if outcomes such as resolution of ear discharge were measured in this way, we planned to report hazard ratios.

For resolution of ear discharge, we extracted the longest available data within the time frame of interest, defined as from one week up to (and including) two weeks (7 days to 14 days), from two weeks up to (and including) four weeks (15 to 28 days), and after four weeks (28 days or one month).

For other outcomes, we reported the results from the longest available follow-up period.

**Extracting data for pain/discomfort and adverse effects**

For these outcomes, there were variations in how studies had reported the outcomes. For example, some studies reported both 'pain' and 'discomfort' separately whereas others did not. We agreed and specified an algorithm for how such data should be extracted, prior to commencement.

We extracted data for serious complications as a composite outcome. If a study reported more than one complication and we could not distinguish whether these occurred in one or more patients, we extracted the data with the highest incidence to prevent double counting.

**Extracting data from figures**

Where values for primary or secondary outcomes were shown as figures within the paper, we attempted to contact the study authors to try to obtain raw values. When raw values were not provided, we extracted information from the graphs using an online data extraction tool, and the best quality version of the relevant figures available.

**Assessment of risk of bias in included studies**

At least two review authors (KH/LVC/CBJ/MJB) independently assessed the risk of bias of each included study. We followed the guidance in the *Cochrane Handbook for Systematic Reviews of Interventions* (*Handbook 2011*), using the Cochrane 'Risk of bias' tool. With this tool we assessed the risk of bias as 'low', 'high' or 'unclear' for each of the following six domains:

- sequence generation;
- allocation concealment;
- blinding of participants, personnel and outcome assessment;
- incomplete outcome data;
- selective reporting;
- other sources of bias.

**Measures of treatment effect**

We summarised the effects of dichotomous outcomes (e.g. proportion of patients with complete resolution of ear discharge) as risk ratios (RR) with confidence intervals (CIs). For the key outcomes that are presented in the 'Summary of findings' tables, we expressed the results as absolute numbers based on the pooled results and compared to the assumed risk. We also planned to calculate the number needed to treat to benefit (NNTB) using the pooled results. The assumed baseline risk was typically either (a) the median of the risks of the control groups in the included studies, this being used to represent a 'medium-risk population' or, alternatively, (b) the average risk of the control groups in the included studies, which is used as the 'study population' (*Handbook 2011*). If a large number of studies had been found, and if appropriate, we would have also presented additional data based on the assumed baseline risk in (c) a low-risk population and (d) a high-risk population.

For continuous outcomes, we expressed treatment effects as a mean difference (MD) with standard deviation (SD). If different scales were used to measure the same outcome, we used the standardised mean difference (SMD) and provided a clinical interpretation of the SMD values.

**Unit of analysis issues**

**Cross-over studies**

This review did not use data from phase II of cross-over studies.

**The ear as the unit of randomisation: within-patient randomisation in patients with bilateral ear disease**

If we had included studies where 'within-patient' randomisation was used (i.e. studies where both ears (right versus left) were randomised), we would have adjusted the analyses for the paired nature of the data (*Elbourne 2002; Stedman 2011*), as outlined in section 16.4 of the *Cochrane Handbook for Systematic Reviews of Interventions* (*Handbook 2011*).

**The ear as the unit of randomisation: non-paired randomisation in patients with bilateral ear disease**

Some patients with bilateral disease may have received the same treatment in both ears, whereas others received a different treatment in each ear. We did not exclude these studies, but we only reported the data if specific pairwise adjustments were completed or if sufficient data were obtained to be able to make the adjustments.

**The patient as the unit of randomisation**

Some studies randomised by patient and those with bilateral CSM received the same intervention for both ears. In some studies the
results may be reported as a separate outcome for each ear (the total number of ears is used as the denominator in the analysis). The correlation of response between the left ear and right ear when given the same treatment was expected to be very high, and if both ears were counted in the analysis this was effectively a form of double counting, which may be especially problematic in smaller studies if the number of people with bilateral CSOM was unequal. We did not exclude these studies, but we only reported the results if the paper presented the data in such a way that we could include the data from each participant only once (one data point per participant) or if we had enough information to reliably estimate the effective sample size or inflated standard errors as presented in chapter 16.3 of the Cochrane Handbook for Systematic Reviews of Interventions (Handbook 2011). If this was not possible, we attempted to contact the authors for more information. If there was no response from the authors, then we did not include data from these studies in the analysis.

If we found cluster-randomised trials by setting or operator, we analysed these according to the methods in section 16.3 of the Cochrane Handbook for Systematic Reviews of Interventions (Handbook 2011).

Dealing with missing data
We attempted to contact the study authors via email whenever the outcome of interest was not reported but the methods of the study had suggested that the outcome had been measured. We did the same if not all of the data required for the meta-analysis was reported, unless the missing data were standard deviations. If standard deviation data were not available, we approximated these using the standard estimation methods from P values, standard errors or 95% CIs if these were reported, as detailed in the Cochrane Handbook for Systematic Reviews of Interventions (Handbook 2011). Where it was impossible to estimate these, we contacted the study authors.

Apart from imputations for missing standard deviations, we did not conduct any other imputations. We extracted and analysed data for all outcomes using the available case analysis method.

Assessment of heterogeneity
We assessed clinical heterogeneity (which may be present even in the absence of statistical heterogeneity) by examining the included studies for potential differences in the types of participants recruited, interventions or controls used, and the outcomes measured. We did not pool studies where the clinical heterogeneity made it unreasonable to do so.

We assessed statistical heterogeneity by visually inspecting the forest plots and by considering the Chi² test (with a significance level set at P value < 0.10) and the I² statistic, which calculated the percentage of variability that is due to heterogeneity rather than chance, with I² values over 50% suggesting substantial heterogeneity (Handbook 2011).

Assessment of reporting biases
We assessed reporting bias as within-study outcome reporting bias and between-study publication bias.

Outcome reporting bias (within-study reporting bias)
We assessed within-study reporting bias by comparing the outcomes reported in the published report against the study protocol, whenever this could be obtained. If the protocol was not available, we compared the outcomes reported to those listed in the methods section. If results were mentioned but not reported adequately in a way that allowed analysis (e.g. the report only mentioned whether the results were statistically significant or not), bias in a meta-analysis was likely to occur. We tried to find further information from the study authors, but if no further information could be obtained, we noted this as being a high risk of bias. Where there was insufficient information to judge the risk of bias, we noted this as an unclear risk of bias (Handbook 2011).

Publication bias (between-study reporting bias)
We intended to create funnel plots if sufficient studies (more than 10) were available for an outcome. If we observed asymmetry of the funnel plot, we would have conducted a more formal investigation using the methods proposed by Egger 1997.

Data synthesis
We conducted all meta-analyses using Review Manager 5.3 (RevMan 2014). For dichotomous data, we analysed treatment differences as a risk ratio (RR) calculated using the Mantel-Haenszel methods. We planned to analyse time-to-event data using the generic inverse variance method if data were available.

For continuous outcomes, if all the data were from the same scale, we pooled the mean values obtained at follow-up with change outcomes and reported this as a MD. However, if the SMD had to be used as an effect measurement, we did not pool change and endpoint data.

When statistical heterogeneity is low, random-effects versus fixed-effect methods yield trivial differences in treatment effects. However, when statistical heterogeneity is high, the random-effects method provides a more conservative estimate of the difference.

Subgroup analysis and investigation of heterogeneity
We subgrouped studies where most participants (80% or more) met the criteria stated below, in order to determine whether the effect of the intervention was different compared to other patients. Due to the risks of reporting and publication bias with unplanned subgroup analyses of trials, we only analysed subgroups reported in studies if these were prespecified and stratified at randomisation.

We planned to conduct subgroup analyses regardless of whether statistical heterogeneity was observed for studies that included patients identified as high-risk (i.e. thought to be less responsive to treatment and more likely to develop CSOM, recurrence or complications) and patients with ventilation tubes (grommets). ‘High-risk’ patients included Indigenous populations (e.g. Australian Aboriginal and Torres Strait Islanders, Native Americans and Inuit populations of Alaska, Canada and Greenland), people with craniofacial malformation (e.g. cleft palate), Down syndrome and people with known immunodeficiency.

We planned to present the main analyses of this review in the form of forest plots based on this main subgroup analysis.
• For the high-risk group, this applied to the following outcomes: resolution of ear discharge (dry ear), quality of life, pain/discomfort, development of complications and hearing loss.

• For patients with ventilation tubes, this applied to a single outcome: resolution of ear discharge (dry ear) for the time period of four weeks or more because this group was perceived to be at lower risk of treatment failure and recurrence than other groups.

If statistical heterogeneity was observed, we also conducted subgroup analysis for the effect modifiers below. If there were statistically significant subgroup effects, we presented these subgroup analysis results as forest plots.

For this review, effect modifiers included:

• **Diagnosis of CSOM**: it was likely that some studies would include patients with chronic ear discharge but who had not had a diagnosis of CSOM. Therefore, we subgrouped studies where most patients (80% or more) met the criteria for CSOM diagnosis in order to determine whether the effect of the intervention was different compared to patients where the precise diagnosis was unknown and inclusion into the study was based purely on chronic ear discharge symptoms.

• **Duration of ear discharge**: there is uncertainty about whether the duration of ear discharge prior to treatment has an impact on the effectiveness of treatment and whether more established disease (e.g. discharge for more than six weeks) is more refractory to treatment compared with discharge of a shorter duration (e.g. less than six weeks).

• **Patient age**: patients who were younger than two years old versus patients up to six years old, versus adults. Patients under two years are widely considered to be more difficult to treat.

We presented the results as subgroups regardless of the presence of statistical heterogeneity based on the following two factors:

• Class of antibiotics. We grouped by pharmacological class, e.g. quinolones, aminoglycosides, penicillins etc. The rationale for this was that different classes may have had different effectiveness and side effect profiles.

• Spectrum of activity against *Pseudomonas aeruginosa* (groups with known activity against *Pseudomonas aeruginosa* versus groups without activity against *Pseudomonas aeruginosa*). This is the most commonly found bacteria in patients with CSOM and its presence is associated with tissue damage.

When other antibiotics were also used as a common treatment in both the intervention and comparison group, we investigated the class and antipseudomonal activity when statistical heterogeneity was present and could not be explained by the other subgroup analyses.

No other subgroups based on the pharmacological properties of antibiotics were planned, but we considered the method and frequency of aural toileting if there was remaining unexplained heterogeneity despite conducting other subgroup analyses.

**Sensitivity analysis**

We planned to carry out sensitivity analyses to determine whether the findings were robust to the decisions made in the course of identifying, screening and analysing the trials. We planned to conduct sensitivity analysis for the following factors, whenever possible:

• Impact of model chosen: fixed-effect versus random-effects model.

• Risk of bias of included studies: excluding studies with high risk of bias (we defined these as studies that have a high risk of allocation concealment bias and a high risk of attrition bias (overall loss to follow-up of 20%, differential follow-up observed)).

• Where there was statistical heterogeneity, studies that only recruited patients who had previously not responded to one of the treatments under investigation in the study. Studies that specifically recruited patients who did not respond to a treatment could potentially have reduced the relative effectiveness of an agent.

If any of these investigations found a difference in the size of the effect or heterogeneity, we mentioned this in the **Effects of interventions** section and/or presented the findings in a table.

**Summary of findings and assessment of the certainty of the evidence**

Using the GRADE approach, at least two review authors (KH/LYC) independently rated the overall certainty of evidence using the GD T tool (http://www.guidelinedevelopment.org/) for the main comparison pairs listed in the **Types of interventions** section. The certainty of evidence reflects the extent to which we were confident that an estimate of effect was correct and we applied this in the interpretation of results. There were four possible ratings: ‘high’, ‘moderate’, ‘low’ and ‘very low’ (Handbook 2011). A rating of ‘high’ certainty evidence implies that we were confident in our estimate of effect and that further research was very unlikely to change our confidence in the estimate of effect. A rating of ‘very low’ certainty implies that any estimate of effect obtained was very uncertain.

The GRADE approach rates evidence from RCTs that do not have serious limitations as high certainty. However, several factors could lead to the downgrading of the evidence to moderate, low or very low. The degree of downgrading was determined by the seriousness of these factors:

• study limitations (risk of bias);

• inconsistency;

• indirectness of evidence;

• imprecision;

• publication bias.

The ‘Summary of findings’ tables present the following outcomes:

• resolution of ear discharge or ‘dry ear’:
  * after four weeks;
  * at between one week and up to two weeks;

• health-related quality of life;

• ear pain (otalgia) or discomfort or local irritation;

• hearing;

• serious complications;

• suspected ototoxicity.
RESULTS

Description of studies

Results of the search

The searches retrieved a total of 8900 references and we identified five additional references from other sources. This was reduced to 3447 after removal of duplicates. We screened the titles and abstracts and subsequently removed 3218 references. We assessed 229 full texts for eligibility, of which we excluded 221 references; we excluded 137 of these references (115 studies) with reasons recorded in the review (see Excluded studies).

We included six references (six studies). There are two studies (two references) awaiting classification, because we were uncertain if the participants were randomised in these studies and are waiting to get a response from the authors (Mehboob 2019; Samarel 2014). See Characteristics of studies awaiting classification. We did not identify any ongoing studies.

A flow chart of study retrieval and selection is provided in Figure 1.
Figure 1. Study flow diagram.

- 8900 records identified through database searching
- 5 additional records identified through other sources ([Helmi 2000; Jamelullah 2016; Roberts 2004; Siddique 2016; Vishwakarma 2015])

- 3447 records after duplicates removed
- 3218 records excluded
- 137 full-text articles (115 studies) excluded, with reasons
- 84 full-text articles excluded, without reasons

- 229 full-text articles assessed for eligibility
- 6 studies (6 references) included in qualitative synthesis
- 2 studies (2 references) are awaiting classification (Mehboob 2019; Samarei 2014)

- 6 studies (5 references) included in
Figure 1. (Continued)

Included studies

We included six studies (de Miguel 1999; Esposito 1990; Esposito 1992; Povedano 1995; Ramos 2003; Yuen 1994). There were two studies that appeared to report on the same set of participants due to the same study design, inclusion criteria, location of study and overlap in key authors (de Miguel 1999; Ramos 2003). Ramos 2003 had 50 participants, rather than 25 per treatment arm, and had an additional treatment arm (six versus five). The proportion of patients achieving resolution of ear discharge was identical. We wrote to the authors to clarify whether these data were obtained from the same set of participants and the authors clarified that these are separate studies. We therefore included both studies in the review.

Table 3 provides a summary of the included studies.

Study design

Three studies were two-arm trials (Esposito 1992; Povedano 1995; Yuen 1994). The remaining three studies were multi-arm trials: Esposito 1990 (three arms), de Miguel 1999 (five arms) and Ramos 2003 (six arms). For this review, only the data that relate to the comparison of topical and systemic antibiotics were included from multi-arm trials. Details of other study arms can be found in the Characteristics of included studies table.

All studies were parallel-group and were reported as "randomised controlled trials". Four studies were from single centres (de Miguel 1999; Esposito 1990; Esposito 1992; Yuen 1994). One was a multicentre study (Ramos 2003). It was unclear in how many centres the remaining study was conducted (Povedano 1995).

Sample size

The total sample size for all of the studies was 445 participants. The sample size by study ranged from 40 to 150, with three of the six studies having 60 participants included.

Unit of randomisation

All studies randomised according to the number of participants, rather than the number of ears. None of the studies provided information regarding methods for assessing ear discharge outcomes in individuals with bilateral disease.

Location

Three studies were conducted in Spain (de Miguel 1999; Povedano 1995; Ramos 2003), two were conducted in Italy (Esposito 1990; Esposito 1992), and one was conducted in Hong Kong (Yuen 1994). See Table 3 for further details.

Setting of trial

Two trials were described as taking place within a university clinic (Esposito 1990; Esposito 1992), and a third was described as being conducted in the ear, nose and throat outpatient clinic of a university hospital (Yuen 1994). Two trials were conducted in a general hospital (de Miguel 1999; Povedano 1995). The final trial was a multicentre study, conducted at three tertiary hospitals (Ramos 2003).

The years in which the studies were conducted was not always well reported. One study was most likely to have been conducted in the 1980s (Esposito 1990). Four further studies were published in the 1990s (de Miguel 1999; Esposito 1992; Povedano 1995; Yuen 1994). The final study was published in 2003 (Ramos 2003). See Table 3 for additional information.

Population

Age and sex

Two studies included a mixture of adults and children. The mean age in de Miguel 1999 was reported as 39.6 years, although 17/125 participants were children. The mean age was not reported by Ramos 2003, but ages ranged from 5 to 73 years old, and 36/300 participants were children.

Four studies included only adult participants (Esposito 1990; Esposito 1992; Povedano 1995; Yuen 1994). The age of participants was reported as a mean of 38 years for Esposito 1990, 44 years for Povedano 1995 and a median of 35 years for Yuen 1994. The mean age was not reported in Esposito 1992.

All studies reported the inclusion of both male and female participants. Five studies reported the characteristics of all individuals randomised in the study (de Miguel 1999; Esposito 1990; Esposito 1992; Povedano 1995; Ramos 2003). Of the 605 individuals included in these trials, 287 (47.4%) were female and 318 (52.6%) were male, with the percentage of females in studies ranging from 44.7% to 58%. One study reported the baseline characteristics for those who completed the trial, excluding those who provided no outcome data, and included 58.9% female and 41.4% male participants (Yuen 1994).

High-risk populations

None of the studies reported the inclusion of any of the ‘high-risk’ populations as defined by our inclusion criteria (cleft palate, Down syndrome, indigenous groups, immunocompromised patients). Esposito 1990 stated that "no patient had diabetes or any other comorbidities".

Diagnosis

CSOM was the main diagnosis for inclusion in four studies (Esposito 1990; Esposito 1992; Povedano 1995; Yuen 1994). Ramos 2003 and de Miguel 1999 included patients with chronic ear discharge, but on a breakdown of the participants more than 50% had CSOM and so we included in the results of this review.
Three studies provided the method for confirmation of diagnosis of tympanic membrane perforation or presence of mucopurulent discharge via otoscopy or microscopic examination (de Miguel 1999; Esposito 1992; Ramos 2003). One further study provided information on the size of the tympanic perforation, therefore we presumed it to have used otoscopic examination (Yuen 1994). The two remaining studies did not describe the diagnostic method used for identifying tympanic membrane perforation (Esposito 1990; Povedano 1995).

**Duration of ear discharge**

Esposito 1992 reported that participants had the presence of discharge for at least 15 days before entering the study. Ramos 2003 stated that discharge was present for "more than 6 weeks or sporadically with 3 or more episodes in the last year". Four studies did not report the duration of ear discharge (de Miguel 1999; Esposito 1990; Povedano 1995; Yuen 1994).

**Other important effect modifiers**

One study did not report on any important effect modifiers (Povedano 1995).

Three studies reported on the number of participants with alternative diagnoses for ear discharge (de Miguel 1999 (n = 17, 13.6%); Ramos 2003 (n = 42, 14%); Yuen 1994 (n = 0, 0%)). Two studies reported on the number of participants who had previously had grommets inserted (Ramos 2003 (n = 12, 4%); Yuen 1994 (n = 0, 0%)).

Two studies reported on the number of participants who had previously had ear surgery (de Miguel 1999; Ramos 2003). The study by de Miguel 1999 reported that 31 participants (24.8%) had ear discharge that occurred after surgery, and Ramos 2003 reported that 73 participants (24.3%) had previous ear surgery. The reasons and type of surgery were not reported in either study. Four studies reported on the number of participants who had received antibiotics for CSOM previously (de Miguel 1999; Esposito 1990; Esposito 1992; Ramos 2003), which ranged from 63% to 67%.

**Intervention**

Details of the intervention, background treatments and treatment durations for each of the included studies are summarised in Table 3.

**Systemic antibiotics**

Four studies included an oral quinolone (ciprofloxacin) as the systemic antibiotic, in doses ranging from 250 mg to 500 mg twice daily (de Miguel 1999; Esposito 1990; Povedano 1995; Ramos 2003).

Esposito 1992 used intramuscular gentamicin (80 mg twice daily) and Yuen 1994 used oral amoxicillin-clavulanic acid (375 mg three times daily).

**Topical antibiotics**

All of the included studies used topical quinolones. Five studies used topical ciprofloxacin drops. Povedano 1995 used twice daily drops (concentration 250 mg/mL, five drops per dose), as did Esposito 1990 (concentration 250 mg/mL, three drops per dose) and Esposito 1992 (concentration 250 mg/mL, four drops per dose). Two studies used two different concentrations of topical ciprofloxacin ear drops (0.2% and 0.5% three times daily). For the purposes of this review we have combined the data from the two groups for analysis (de Miguel 1999; Ramos 2003).

One study used topical ofloxacin ear drops (0.3%, three times daily; Yuen 1994).

**Background treatment**

Two studies reported aural toileting at baseline. This included aspiration and cleaning of secretions in one study (de Miguel 1999), and suction clearance of aural pus under microscopy for the second study (Yuen 1994). The remaining four studies did not mention the use of any aural toileting (Esposito 1990; Esposito 1992; Povedano 1995; Ramos 2003).

**Duration of intervention**

All six studies had a duration of intervention of two weeks or less. Three studies treated participants for seven days (de Miguel 1999; Ramos 2003; Yuen 1994). Two studies treated participants for a minimum of five days; patients who were not 'cured' by five days continued treatment until they were cured, up to a maximum of 10 days (Esposito 1990; Esposito 1992). The final study treated participants for 10 days (Povedano 1995).

**Comparisons**

Four studies compared topical quinolones to oral quinolones:

- de Miguel 1999 - topical ciprofloxacin versus oral ciprofloxacin.
- Esposito 1990 - topical ciprofloxacin versus oral ciprofloxacin.
- Povedano 1995 - topical ciprofloxacin versus oral ciprofloxacin.
- Ramos 2003 - topical ciprofloxacin versus oral ciprofloxacin.

One study compared a topical quinolone to an intramuscular aminoglycoside:

- Esposito 1992 - topical ciprofloxacin versus intramuscular gentamicin.

One study compared a topical quinolone to an oral penicillin with beta-lactamase inhibitor:

- Yuen 1994 - topical ofloxacin versus oral amoxicillin-clavulanic acid.

**Outcomes**

**Resolution of ear discharge**

The definitions, methods and timing of assessment differed between studies, and these are summarised in Table 4.

**Health-related quality of life using a validated instrument**

No studies reported on health-related quality of life.

**Ear pain (otalgia) or discomfort or local irritation**

No studies specifically reported on ear pain, discomfort or local irritation. Two studies reported that no side effects were reported by any participant, but it is unclear whether this included ear pain, discomfort or irritation (Esposito 1990; Esposito 1992).

**Hearing**

Four studies indicated that they measured hearing after treatment, but did not provide information on the frequencies that were
tested, or any data on the outcome (Esposito 1990; Esposito 1992; Ramos 2003; de Miguel 1999). One study indicated the frequencies at which hearing was tested (0.5 kHz, 1 kHz, 2 kHz and 4 kHz), but only reported the results narratively (Yuen 1994).

**Serious complications (including intracranial complications, extracranial complications and death)**

No study reported any serious complications.

**Suspected ototoxicity**

Four studies reported on ototoxicity in some way, but there was a lack of clarity over the methods used to assess this (de Miguel 1999; Esposito 1992; Ramos 2003; Yuen 1994). Three studies indicated that post-treatment audiometry was performed to assess ototoxicity, but no definition of ototoxicity was provided (de Miguel 1999; Esposito 1992; Ramos 2003). One study reported carrying out pre- and post-treatment audiograms of bone conduction thresholds at frequencies of 0.5 kHz, 1 kHz, 2 kHz and 4 kHz but it was not clear if there was a difference between groups in the results, which were reported narratively (Yuen 1994).

**Funding**

Esposito 1990 and Esposito 1992 reported receiving the intervention medication from a pharmaceutical company. One study reported financial support from a research grant, but no pharmaceutical funding (Yuen 1994). The remaining three studies did not provide any information on funding sources (de Miguel 1999; Povedano 1995; Ramos 2003).

**Declarations of interest**

None of the included studies provided any information on declarations of interest from the authors.

**Excluded studies**

We excluded 137 papers (115 studies) after reviewing the full text. Further details for the reasons for exclusion can be found in the Characteristics of excluded studies table. These are the main reasons for exclusion:

We excluded 32 studies (35 references) due to the population characteristics included in their study (Abbott 2016; Adler 2000; Baba 1982b; Baba 1983; Baba 1983b; Baba 1983c; Baba 1987; Berman 1990; Block 2000; Bogomil’ski 1999; Bros Soriano 1996; Clayton 1990; Garcia-Rodriguez 1993; Granath 2007; Gyde 1981; Gyde 1982; ICRCT20130427013136N6; ICRCT2016082313136N4; Kovacic 1999; Kurilin 1969; Liv 1990; Merifield 1993; Morgan 1992; Olaya 1983; Mesure 1973; Principi 1995; Quick 1973; Quick 1975; Roberts 2004; Saez-Llorens 2005; Stenstrom 1991; von Dongen 2014).

We excluded nine studies (10 references) as the interventions were outside of our protocol (Browning 1983; Browning 1983b; Connolly 1997; CTRI/2019/09/021197; Dellamonica 1995; ISRCTN12149720; ISRCTN84220085; Jiang 2016; Khanna 2000; Li 2004).

Six studies (six references) had multiple reasons for exclusion (Baba 1980; Fombeur 1994; Hemlin 1997; Kashiwamura 2004; Khon 2012; Thomsen 1976).

**Risk of bias in included studies**

See Figure 2 for the 'Risk of bias' graph (our judgements about each risk of bias item presented as percentages across all included studies) and Figure 3 for the 'Risk of bias' summary (our judgements about each risk of bias item for each included study).

**Figure 2. 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.**
Figure 3. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.

Topical versus systemic antibiotics for chronic suppurative otitis media (Review)

Allocation

Randomisation

We judged one study to have had adequate sequence generation (Yuen 1994). We assessed one study as having a high risk of bias as more than half of the patients (38/60) were previously unsuccessfully treated with at least five days of antibiotics, and it was unclear whether this was distributed across groups in a balanced manner (Esposito 1990). In addition, a higher proportion of patients (12/20) in the oral ciprofloxacin only group had Pseudomonas compared to the other groups (8/20), introducing a high risk of bias. The remaining four studies did not describe the method of sequence generation and we considered all of these to have unclear risk of bias.

Allocation concealment

We assessed one study to be at low risk of bias (Yuen 1994). We judged the remaining five studies as being at unclear risk of bias as they did not describe the methods used for allocation concealment.

Blinding

Performance bias

All six of the studies were non-blinded and treatments were administered by the patients. Therefore, we assessed the risk of performance bias as high.

Detection bias

We assessed one study as having low risk of bias, as they described how they had attempted to blind the outcome assessors (Yuen 1994). We assessed the remaining five studies as being at high risk as they did not describe any attempts to blind outcome assessors and the outcomes assessed were subjective.

Incomplete outcome data

We assessed the risk of attrition bias as low for four studies (Esposito 1992; Povedano 1995; Ramos 2003; Yuen 1994). We assessed two studies as being at unclear risk of bias as the number of dropouts was not reported (de Miguel 1999; Esposito 1992).

Selective reporting

No protocols were available for any of the six studies. We assessed two studies as being at high risk of bias as some of the results mentioned in the methods section were not fully presented in the results section (Esposito 1990; Esposito 1992). For Esposito 1990, "cure" or resolution of discharge was only reported at one time point, most likely at 14 days after the end of treatment, but the results at other time points are described in the methods section of the paper (24 hours after the end of treatment, i.e. 6 to 11 days) and these were not reported. Similarly, Esposito 1992 showed a table of the number of people who were "cured", "improved" or "failed" treatment, but did not indicate the time point of measurement, and two of the time points measured were not reported. We assessed the remaining four studies as being at unclear risk of bias for selective reporting.

Other potential sources of bias

The studies did not describe how outcomes were measured and defined for patients with bilateral ear disease. Based on the information reported and the nature of the comparison, we assumed that the studies had randomised by patient and the number of events corresponds to patients rather than ears.

Effects of interventions

See: Summary of findings 1 Topical quinolone compared to oral quinolone for chronic suppurative otitis media; Summary of findings 2 Topical quinolone compared to intramuscular gentamicin for chronic suppurative otitis media; Summary of findings 3 Topical quinolone compared to oral amoxicillin-clavulanic acid combination for chronic suppurative otitis media

Comparison 1: Topical quinolone versus oral quinolone

Four studies (325 participants) were included in this comparison (Table 3):

- de Miguel 1999 (75 participants): topical ciprofloxacin (0.2% or 0.5%, three drops three times daily) against oral ciprofloxacin (500 mg twice daily) for 7 days.
- Esposito 1990 (40 participants): topical ciprofloxacin (250 μg/mL, three drops twice daily) against oral ciprofloxacin (250 mg twice daily) for up to 10 days.
- Povedano 1995 (60 participants): topical ciprofloxacin (250 μg/mL, five drops twice daily) against oral ciprofloxacin (500 mg twice daily) for 10 days.
- Ramos 2003 (150 participants): topical ciprofloxacin (0.2%/0.5%, 0.5 mL three times daily) against oral ciprofloxacin (500 mg twice daily) for 7 days.

In these studies, aural toileting was either not mentioned or limited to the first visit. See Summary of findings 1.

Resolution of ear discharge or ‘dry ear’

Between one week and up to two weeks

Topical quinolones may be slightly more effective at resolving ear discharge at one to two weeks than oral quinolones (risk ratio (RR) 1.48, 95% confidence interval (CI) 1.24 to 1.76; 285 participants; 3 studies; I² = 0%; low-certainty evidence; Figure 4; Analysis 1.1).
Figure 4. Forest plot of comparison: 1 Topical quinolone versus oral quinolone, outcome: 1.1 Resolution of ear discharge.

Test for subgroup differences: Chi² = 1.43, df = 1 (P = 0.23), I² = 29.8%

Two weeks to up to four weeks
Esposito 1990 reported resolution of ear discharge at two to four weeks (RR 2.13, 95% CI 1.20 to 3.75; 40 participants).

After four weeks
None of the studies reported results after four weeks.

Health-related quality of life using a validated instrument
None of the studies reported this outcome.

Ear pain (otalgia) or discomfort or local irritation
None of the studies reported this outcome.

Hearing
Although three studies reported hearing as an outcome in their methods section (de Miguel 1999; Esposito 1990; Ramos 2003), none of them reported results for this outcome.

Serious complications (including intracranial complications, extracranial complications and death)
None of the studies reported this outcome.

Suspected ototoxicity
Three studies reported that they did not suspect ototoxicity in any participants, but it is unclear how this was measured (de Miguel 1999; Esposito 1990; Ramos 2003) (very-low certainty evidence).

de Miguel 1999 reported that the data did not show cochleovestibular dysfunction during treatment or further follow-up. They also stated that all post-treatment audiometry showed no evidence of ototoxicity, either for the oral or topical routes. However, no definition of 'ototoxicity' was provided and it is likely to be standard audiometry rather than bone conduction studies.

Esposito 1990 stated that "no side effect was recorded in any patient and no worsening of the audiometric function related to the local therapy was observed". Audiometric measurement and vestibular tests were performed before and 24 hours after the end of the therapy in patients receiving topical treatment only.

Ramos 2003 reported a lack of symptoms suggesting vestibular problems, but did not provide details on how this was measured or defined.

Subgroup analysis
We did not undertake any subgroup analysis as there were no differences in any of the identified studies with regards to the planned subgroups.

Comparison 2: Topical quinolone versus intramuscular gentamicin
Only one study (Esposito 1992; 60 participants) compared topical ciprofloxacin (250 mg/mL, twice daily) with intramuscular gentamicin injections (80 mg twice daily) for up to 10 days. No concurrent treatments or aural toileting were reported (see Summary of findings 2).

Resolution of ear discharge or 'dry ear'
Between one week and up to two weeks
The study did not report results for this time point.

Between two weeks and up to four weeks
Topical ciprofloxacin may increase the resolution of ear discharge at two to four weeks compared to intramuscular gentamicin, but the evidence is very uncertain (RR 1.92, 95% CI 1.24 to 2.98; 60 participants; Figure 5; Analysis 2.1).

Subgroup analysis

With only one study included in the quantitative analysis, subgroup analysis was not possible.

Comparison 3: Topical quinolone versus (oral) systemic beta-lactams

Only one study (Yuen 1994; 60 participants) compared ofloxacin ear drops (0.3% three times daily) with oral amoxicillin-clavulanic acid (375 mg, three times daily) for seven days. All participants underwent ear cleaning at the first treatment but no other concurrent treatments were mentioned (see Summary of findings 3).

Resolution of ear discharge

Between one week and up to two weeks

We are uncertain if topical ofloxacin ear drops increase resolution of ear discharge compared with oral amoxicillin-clavulanic acid as although Yuen 1994 (56 participants) reported an increase in resolution with topical ofloxacin, the limitations in the study and small sample size reduce our certainty in the result (RR 2.93, 95% CI 1.50 to 5.72; 56 participants, very low-certainty evidence; Figure 6; Analysis 3.1).

After four weeks

The study did not report results for this time point.

Health-related quality of life using a validated instrument

Esposito 1992 did not report this outcome.

Ear pain (otalgia) or discomfort or local irritation

Although this outcome was not specifically reported by Esposito 1992, the authors reported that "no side effect was recorded in any patient" (very low-certainty evidence).

Hearing

Esposito 1992 indicated that audiometry was performed after treatment, but only reported that "no worsening of the audiometric function related to local or parenteral therapy was observed" (very low-certainty evidence).

Serious complications (including intracranial complications, extracranial complications and death)

Esposito 1992 reported that "no side effect was recorded" and did not report that any participant died or had any intracranial or extracranial complications (very low-certainty evidence).

Suspected ototoxicity

Audiometric measurement and vestibular tests were performed before and 24 hours after the end of the therapy and "no side effect was recorded" (very low-certainty evidence).

Figure 6. Forest plot of comparison: Topical quinolone versus oral amoxicillin-clavulanic acid, outcome: 2.1 Resolution of ear discharge.
One participant was excluded from this analysis as they discontinued treatment. We conducted a sensitivity analysis to assess the effect of re-including this participant, with the assumption that they were not cured by the intervention. The results remained in favour of topical ofloxacin (RR 3.03, 95% CI 1.55 to 5.95; Analysis 3.2).

**Two weeks to up to four weeks**
The study did not report results for resolution of ear discharge at this time point.

**After four weeks**
The study did not report results for this time point.

**Health-related quality of life using a validated instrument**
Yuen 1994 did not report this outcome.

**Ear pain (otalgia) or discomfort or local irritation**
Although this outcome was not specifically reported, Yuen 1994 reported that "no patient of the ofloxacin-treated group complained of adverse side effects. There was no hypersensitivity reaction to the topical ofloxacin" (very low-certainty evidence).

**Hearing**
Yuen 1994 reported that "there were no significant differences between the pre-treatment and post-treatment pure-tone audiograms of bone conduction thresholds at frequencies of 0.5, 1, 2, and 4kHz" (very low-certainty evidence). No further details were provided.

**Serious complications (including intracranial complications, extracranial complications and death)**
Yuen 1994 did not report did not report this outcome.

**Suspected ototoxicity**
Although Yuen 1994 reported the use of patient diaries to record tinnitus and dizziness, the results for this were not reported. Bone conduction studies were also completed and the study authors reported that "there were no significant differences between the pre-treatment and post-treatment pure-tone audiograms of bone conduction thresholds at frequencies of 0.5, 1, 2, and 4kHz" (very low-certainty evidence). No further details were provided.

**Subgroup analysis**
With only one study included in the quantitative analysis, subgroup analysis was not possible.

**DISCUSSION**

**Summary of main results**
We included six studies reporting on three different comparisons. Due to the choice of outcome measures used in these studies and the incomplete reporting of results, for many of the proposed comparisons we were not able to find a substantial amount of evidence.

**Comparison 1. Topical versus systemic administration of the same type of antibiotics (quinolones)**
We included four studies (325 participants), which compared topical versus systemic (oral) administration of ciprofloxacin and found that topical administration may slightly increase resolution of ear discharge at one to two weeks compared with systemic administration (risk ratio (RR) 1.48, 95% confidence interval (CI) 1.24 to 1.76; 285 participants; 3 studies; I² = 0%; low-certainty evidence). In these studies, aural toileting was either not mentioned or limited to the first visit. Resolution at two to four weeks was also higher for the topical quinolone group (RR 2.13, 95% CI 1.20 to 3.75; 40 participants; 1 study). The studies did not report outcomes beyond four weeks. Two studies reported otoscopic confirmation of CSOM, whilst the other two studies were unclear. Three studies reported that they did not suspect ototoxicity in any participants, but it is unclear how this was measured (very low-certainty evidence). No studies reported on health-related quality of life, ear pain/discomfort/irritation or serious complications, and no data were presented for hearing outcomes despite three studies describing it as having been measured. See Summary of findings 1.

**Comparison 2. Topical versus systemic administration of different types of antibiotics (topical quinolones versus systemic aminoglycosides)**
We included one study (60 participants), which compared topical ciprofloxacin against gentamicin injected intramuscularly. No aural toileting was reported. No results for resolution of ear discharge were presented at either one to two weeks or after four weeks. At two to four weeks of follow-up, although the authors reported a higher resolution rate in the topical quinolone group (RR 1.92, 95% CI 1.24 to 2.98; 60 participants), we are very uncertain about this finding due to study limitations and imprecision. It was unclear if this study used otoscopic confirmation of CSOM. The study did not report any "side effects", from which we assumed no ear pain, suspected ototoxicity or serious complications occurred (very low-certainty evidence). The study stated that "no worsening of the audiometric function related to local or parenteral therapy was observed" (very low-certainty evidence). Health-related quality of life was not reported. See Summary of findings 2.

**Comparison 3. Topical versus systemic administration of different types of antibiotics (topical quinolones versus systemic amoxicillin-clavulanic acid)**
One study compared topical ofloxacin versus oral amoxicillin-clavulanic acid, where all participants underwent suction clearance at the first visit. This study found that topical quinolones may result in more people having resolution of ear discharge at one to two weeks of follow-up (RR 2.93, 95% CI 1.50 to 5.72; 56 participants, very low-certainty evidence), but the very small sample size and study limitations reduced our certainty in the results. It was unclear if this study used otoscopic confirmation of CSOM. The study reported no adverse events in the topical antibiotic group, including otalgia (ear pain) and hypersensitivity reactions. There were no significant differences in hearing (air conduction hearing levels) reported (very low-certainty evidence). Potential ototoxicity was measured in the topical antibiotic group with bone-conduction audiometry and it was reported that there was no difference between pre- and post-treatment bone-conduction hearing levels. Participants were asked to record any tinnitus, dizziness or suspected hearing loss symptoms, but reporting was
limited to a statement that "none complained of adverse side effects" in the topical antibiotic group. Health-related quality of life and serious complications were either not measured or not reported. See Summary of findings 3.

**Overall completeness and applicability of evidence**

The overall completeness of the evidence base was very limited. Only six studies were available over the three comparisons, and only a single study was included for each of the second and third comparisons. All studies were conducted at tertiary or secondary care centres including hospital departments and specialist clinics. All studies were published at least 15 years ago (and up to 30 years ago). Two studies reported otoscopic confirmation of CSOM whilst for four studies this was unclear. Although we planned subgroup analyses for different participant characteristics (age, high-risk, ventilation tubes), treatment duration and spectrum of antibiotic activity, these were not carried out because the data were not available, data were not clearly reported or heterogeneity was not observed. No studies examined children under two years of age and this leaves us with no information on this important patient group. No studies included participants classified as 'high-risk' in our protocol. Patients in these high-risk groups can be a challenge for clinicians to treat effectively and evidence to support best-practice interventions for these people is needed. All studies were conducted in high-resource settings in Western Europe and East Asian countries (five in Western Europe, one in China (Hong Kong)), which have a below average estimated incidence of CSOM of fewer than four cases per thousand people (Monasta 2012).

Disease in low-resource settings may be more severe as well as more prevalent.

Two of the commonly used topical antibiotics were quinolones and aminoglycosides. Although we have limited evidence showing that topical application of quinolones may be slightly more effective with respect to resolution of ear discharge than systemic (oral) quinolones at one to two weeks, we have not found any studies comparing topical versus systemic aminoglycosides. Therefore, we are unable to generalise with regard to whether topical administration of antibiotics is always better than systemic administration when the same type or class of antibiotics is used. The spectrum of activity and bioavailability of antibiotics are factors that might influence their effectiveness by different routes of administration.

We are also unable to compare the safety of topical versus systemic aminoglycosides regarding the risk of ototoxicity. Whilst there were no significant differences reported in mean hearing levels or suspected worsening of audiological measurements, the outcome was poorly reported across all studies. The efficacy of topical compared to systemic antibiotics is likely to be influenced by the sensitivity of the micro-organisms present to the antibiotic used. We were unable to carry out a subgroup analysis of the spectrum of antibiotic activity as the data were either not in the included studies or heterogeneity was not observed, which leaves us with no information on this aspect of antibiotic treatment. Aural toileting prior to application of topical antibiotics may also influence the effectiveness of topical antibiotic treatment. All the studies included had limited use of aural toileting, either only mentioning microsuction in the initial assessment (two studies), or not mentioning any form of aural toileting (four studies).

There were very few data for outcomes other than resolution of ear discharge. No studies reported health-related quality of life. Adverse events, suspected ototoxicity and serious complications were all poorly reported. The length of follow-up in all studies was between one and four weeks, meaning that there was limited evidence regarding the long-term effectiveness of topical versus systemic antibiotics for the resolution of discharge for people with CSOM.

**Quality of the evidence**

The certainty of the evidence for all outcomes in these comparisons was low or very low (GRADE assessment). This was mainly due to two factors: the risk of bias in the studies and imprecision. In many cases the results were imprecise due to the small number of participants available for analysis (resulting in large confidence intervals). There were important limitations in the methods of study conduct and reporting in nearly all of the studies. Five (of six) of the studies had unclear randomisation and allocation concealment and none of the studies blinded participants or study personnel to treatment group.

Accuracy of the diagnosis was also a potential issue throughout the studies included in this review. Of the six included studies, only two described the use of otoscopic confirmation of resolution of discharge. This may have impacted on the accuracy of the diagnostic outcome and therefore the response to treatment.

**Potential biases in the review process**

Within this series of CSOM Cochrane Reviews the potential for publication bias has been identified as an issue. In some reviews, unpublished studies were found and included in the review (Brennan-Jones 2020a; Brennan-Jones 2020b; Head 2020a; Head 2020b), and there is a suspicion that further unpublished trials may have been completed. It is unknown whether this is a risk with this review.

**Agreements and disagreements with other studies or reviews**

This review is part of a series of reviews on CSOM (Bhutta 2020; Brennan-Jones 2020a; Brennan-Jones 2020b; Head 2020a; Head 2020b). A companion review looks at the effectiveness of systemic antibiotics for the treatment of CSOM (Chong 2021).

Two other reviews evaluated whether topical and systemic antibiotics are effective for the treatment of CSOM (Brennan-Jones 2020a and Chong 2021, respectively), and provided information that is complementary to the findings of this review. The potential ototoxicity of topical quinolones versus topical aminoglycosides was also compared in another review in this series (Brennan-Jones 2020a). In Brennan-Jones 2020a, topical antibiotics were compared against placebo and other types of topical antibiotics. Despite the serious limitations of the evidence (very low-certainty), the review suggested that topical antibiotics (aminoglycosides and quinolones) may be effective (compared to a placebo) as a single treatment, and when used on top of systemic antibiotics. The efficacy of the addition of topical steroids to topical antibiotics for the treatment of CSOM was also included in this suite of reviews. Given the very low certainty of the evidence included, it was not clear whether there was any benefit to adding a steroid to topical antibiotics alone, in terms of resolution of ear discharge (Brennan-Jones 2020b).
There are few previous reviews or guidelines for CSOM. The World Health Organization (WHO) in 2004 suggested that first-line treatment of CSOM should comprise aural toilet and topical antibiotic drops, with second-line treatment comprising an alternative topical antibiotic (guided by the results of microbiological culture) or parenteral antibiotics (WHO 2004). The Australian government recommendations from 2010 for the treatment of Aboriginal and Torres Strait Islanders gave similar recommendations, with first-line treatment comprising aural toilet (or antiseptic washout) followed by topical antibiotics, and second-line treatment with parenteral antibiotics (Morris 2010). An expert panel of the American Academy of Otolaryngologists in 2000 came to a similar conclusion (Hannley 2000).

**AUTHORS’ CONCLUSIONS**

**Implications for practice**

There is a limited amount of low-quality evidence available to examine whether topical or systemic antibiotics are more effective in achieving resolution of ear discharge for people with CSOM. However, amongst this uncertainty there is some evidence to suggest that the topical administration of antibiotics may be slightly more effective than systemic administration in achieving resolution of ear discharge (dry ear) at one to two weeks. There is limited evidence available regarding different types of antibiotics. It is not possible to determine with any certainty whether quinolones are better or worse than aminoglycosides. These two groups of compounds have different adverse effect profiles, but there is insufficient evidence from the included studies to make any comment about these. In general, adverse effects were poorly reported.

**Implications for research**

The results of this review, current to March 2020, show that there is low-certainty evidence that, for people with CSOM, treatment with topical antibiotics may be beneficial in improving the short-term resolution of ear discharge when compared to a systemic antibiotic. Potential adverse effects and hearing outcomes were poorly reported and the impact of background treatment with aural toileting is also unclear. The low certainty of the evidence for CSOM treatments in this review is common throughout this suite of seven reviews of CSOM treatments.

There is insufficient evidence to address the efficacy and harms of antibiotics for high-risk groups such as immunocompromised patients or Indigenous populations.

Prior to commencing these reviews, we conducted a scoping review that identified one key question that clinicians, researchers and consumers would like to see answered from this review:

- What are the relative effects of topical antibiotics compared with the same systematic antibiotics?

Due to the low certainty of the available evidence this question cannot yet be addressed with any certainty. There is clearly room for more trials examining the impact of antibiotics for people with CSOM, including trials that assess the route of administration, the class of antibiotic and the dosing/duration. Whilst the largest number of studies compared the use of topical quinolones to systemic quinolones, the certainty of the evidence is still very low (GRADE) for this comparison.

Long-term effects (effectiveness and harms) are also important. In addition to clinical trials, health services should establish prospective databases for patients with CSOM to record (long-term) outcomes for resolution of discharge, adverse effects and hearing outcomes for people receiving treatment.

**Suggestions for future trials**

This review is one of a suite of reviews of treatments for CSOM, each of which features its own research recommendations. Across all reviews, key features of future research are as follows:

**Design and methods**

- Where the intent is to assess the effectiveness of interventions, randomised controlled trials should be conducted. These trials (including those testing non-systemic interventions) should randomise, analyse and report results by person (not ears) to avoid double counting.
- In patients with bilateral CSOM, for outcomes that can be reported by ear, such as resolution of ear discharge or recurrence, only one finding should be analysed and reported per person. We suggest that a single ear be included in the trial (the decision on which ear is to be included and analysed must be made a priori, and the method or criteria for the decision must explicitly specified in the trial protocol and report). Since there are limited data on whether people with bilateral CSOM respond to treatment in the same way as people with unilateral CSOM, and whether both ears respond in the same way to treatment, reporting these factors would be useful.
- Trials need to use appropriate methods for randomisation and allocation concealment to avoid selection bias, and they should be adequately powered.
- Attempts should be made by the investigators to blind participants, healthcare professionals and study personnel to the treatment allocation. This could be through the use of a placebo and ensuring that the treatment regimens are the same between treatment arms. A double placebo design should be used where dosage form and/or regimen are different. Where it is not possible to blind participants and/or clinicians to the treatment received, efforts to blind the outcome assessment and analysis personnel should be made.

**Population**

- Diagnosis of CSOM should be according to the World Health Organization criteria (WHO 2004), be otoscopically confirmed, include an assessment of hearing level, and record the duration of discharge.
- Potentially important patient characteristics (such as presence of ear grommets) should be recorded and presented in the report.
- If patients from 'high-risk' groups are included, these characteristics should be accounted for and explored in the design of the study.

**Interventions**

- All interventions (adjunctive therapies and/or allowed treatment) should be the same apart from the treatments being evaluated.
- Clear reporting of the therapies used, including dose, frequency and duration, and clear descriptions of any adjunctive therapies
used across the treatment groups (including aural toileting), should be provided.

Outcomes

- There is currently no core outcome set for CSOM, or a widely agreed set of priority outcomes and definitions for CSOM trials. The development of core outcome sets for CSOM, using established methods (Kirkham 2017), would be beneficial for future trials. This would help to ensure that trials are consistent, high-quality and examine appropriate outcomes. The standardisation of outcomes allows for analysis and comparison of data across trials (and treatments) using network meta-analysis or individual participant data meta-analysis.
- The assessment of adverse effects should be defined in the protocol and these should be systematically sought during trials using explicit methods.
- All outcomes (including hearing and balance) should be measured and reported using valid and predefined methods.
- A validated quality of life instrument should be used whenever possible.
- Studies should follow up patients for at least six months and preferably over one year to identify the rate of recurrence of ear discharge, using a pre-agreed definition of recurrence.
- Trials should be registered in a regional or international clinical trials registry and, when published, adhere to reporting guidelines such as CONSORT (CONSORT 2010). Where publication in a peer-reviewed journal is not possible, results should be included in the clinical trial report.

ACKNOWLEDGEMENTS

We are grateful to Mr Iain Swan for peer reviewing the protocol and review, and to consumer referee Joan Blakely for her helpful comments at all stages. We would also like to thank Dr Adrian James, as Acting Co-ordinating Editor for Cochrane ENT, for his insightful comments and advice, and the other members of the Cochrane ENT editorial board for their input and encouragement. We would like to sincerely thank Jenny Bellerini and Samantha Cox from the Cochrane ENT team for their invaluable help, which has enabled the completion of this suite of reviews. In addition, we thank Professor Amanda Leach for her contributions towards the project and we are grateful to Takashi Fujiwara, Maria Paula Garcia and Rina Shoki for assisting with the data extraction and risk of bias assessments.

We would also like to thank the following clinicians, scientists and consumers who provided comments on the initial scoping review and prioritisation exercise for this suite of reviews into CSOM: Amanda Leach, Chris Perry, Courtney McMahen, De Wet Swanepeol, Deborah Lehmann, Eka Dian Safitri, Francis Lannigan, Harvey Coates, Has Gunasekera, Ian Williamson, Jenny Reath, Kathy Brooker, Kathy Currie, Kelvin Kong, Matthew Brown, Pavanee Intakorn, Penny Abbott, Samantha Harkus, Sharon Weeks, Shelly Chadha, Stephen O’Leary, Victoria Stroud and Yupitri Pitoyo.

We are also indebted to Erika Ota from Cochrane Japan for organising a group of MSc students, Shunka Cho, Kiriko Sasayama, Asuka Ohashi, Noyuri Yamaji and Mika Kato, to help with translating and identifying primary studies for inclusion or exclusion for this suite of reviews.

This project was funded by the NHMRC Centre of Research Excellence in Ear and Hearing Health of Aboriginal and Torres Strait Islander Children (NHMRC CRE _ITCHEAR). The contents of the publications arising from this work are solely the responsibility of the authors and do not reflect the views of NHMRC.

This project was supported by the National Institute for Health Research, via Cochrane Infrastructure, Cochrane Programme Grant or Cochrane Incentive funding to Cochrane ENT. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the Systematic Reviews Programme, NIHR, NHS or the Department of Health.

## Characteristics of included studies [ordered by study ID]

### de Miguel 1999

**Study characteristics**

<table>
<thead>
<tr>
<th>Methods</th>
<th>5-arm, non-blinded, parallel-group RCT, with 7 days duration of treatment and 15 days duration of follow-up</th>
</tr>
</thead>
</table>
| Participants | **Location**: Canary Islands, Spain  
**Setting of recruitment and treatment**: general hospital, published in 1999  
**Sample size**: 125  
| **Participant (baseline) characteristics**: |  
- **Age (mean, range)**: 39.6 years, 6 to 83, but 17/125 of participants were children  
- **Gender (F/M)**: 56 (44.8%)/69 (55.2%)  
- **Main diagnosis**: chronic otitis media, which comprised the following groups:  
  * Simple chronic otitis media - no osteitic changes, tympanosclerosis or cholesteatoma (n = 45)  
  * Osteitic chronic otitis media - with changes to the ossicular chain and some permanent alterations in the mucosa (tympanosclerosis or chronic granulomatosis) (n = 32)  
  * Cholesteatomatous chronic otitis media (n = 17)  
  * Post-surgery cases (n = 31)  
- **High-risk population**:  
  * Cleft palate (or other craniofacial malformation): not reported  
  * Down syndrome: not reported  
  * Indigenous groups (Australian Aboriginals/Greenland natives): not reported  
  * Immunocompromised: not reported  
- **Diagnosis method**:  
  * Confirmation of perforated tympanic membrane: all patients had otoscopy under microscopy at entry. 51.2% had "non-marginal tympanic perforation". The involvement of the ossicular chain in the otological microscopic examination was found in 43.2% of the patients.  
  * Presence of mucopurulent discharge: 113/125 (90.4%), 89/125 (71.2%) with odorous discharge  
  * Duration of symptoms (discharge): not reported  
- **Other important effect modifiers**:  
  * Alternative diagnosis of ear discharge: cholesteatoma (n = 17)  
  * Patients with discharge after operation: unclear type/reason for operations (n = 31)  
  * Number who have previously had grommets inserted: not reported  
  * Number who have had previous ear surgery: at least 31/125 (24.8%), reasons and type of surgery not reported  
  * Number who had previous antibiotic treatment for CSOM: 79/125 (63.2%) |

**Inclusion criteria**:  
- Patients (adults and children) with chronic otitis media, presenting with chronic otorrhoea as major symptom. Diagnostic criteria not reported.  

**Exclusion criteria**: not reported

Group C (n = 25): topical ciprofloxacin 0.5%, 3 ear drops/8 hours for 7 days

Group D (n = 25): topical ciprofloxacin 0.2%, 3 ear drops/8 hours for 7 days and oral ciprofloxacin, 500 mg/12 hours for 7 days simultaneously

Group E (n = 25): topical polymixin B + neomycin + hydrocortisone, 3 ear drops/8 hours for 7 days

Concurrent treatment: all patients had aspiration and cleaning of ear secretions before beginning treatment; analgesics and antipyretics

Outcomes of interest in the review:

Primary outcome:
- Resolution of ear discharge at 1 to 2 weeks. Unclear if otoscopically confirmed.

Secondary outcomes:
- Hearing: hearing tests at time of diagnosis, at 8 days and at 15 days
- Suspected ototoxicity

Funding sources: No information provided

Declarations of interest: No information provided

Notes: Unit of randomisation: person

Methods for including patients with bilateral disease: not reported

#### Study characteristics

**Methods**

3-arm, non-blinded, parallel-group RCT, with 5 to 10 days of treatment and 24 hours and 14 days follow-up after end of treatment

**Participants**

**Location:** Naples, Italy, 1 site

**Setting of recruitment and treatment:** Clinic of Infectious Diseases and Otolaryngology, University of Naples

**Sample size:**

- Number randomised: 20 in each intervention
- Number completed: 20 in each intervention

**Participant (baseline) characteristics:**

- Age: mean 38 years
- Gender (F/M): 29 (48%)/31 (52%)
- Main diagnosis: mild or moderate CSOM in the acute stage
- High-risk population: no
  * Cleft palate (or other craniofacial malformation): not reported
  * Down syndrome: not reported
  * Indigenous groups (Australian Aboriginals/Greenland natives): not reported
  * Immunocompromised: “no patients had diabetes or any other comorbidities”
- Diagnosis method:
  * Confirmation of perforated tympanic membrane: not reported
  * Presence of mucopurulent discharge: not reported
  * Duration of symptoms (discharge): not specified
- Other important effect modifiers:
  * Alternative diagnosis of ear discharge: not reported
  * Number who have previously had grommets inserted: not reported
  * Number who have had previous ear surgery: not reported
  * Number who had previous antibiotic treatment for CSOM: 38/60 (63%) had at least 5 days of antibiotics and did not respond
- Inclusion criteria:
  * Mild to moderate chronic otitis media in acute stage without cholesteatoma or mastoiditis
- Exclusion criteria:
  * Younger than 18 years old
  * Cholesteatoma
  * Mastoiditis

**Interventions**

- **Topical plus systemic ciprofloxacin (n = 20):** 3 drops topical ciprofloxacin 250 μg/mL in saline solution locally twice a day PLUS oral ciprofloxacin 250 mg twice a day until cure or up to 10 days
- **Topical ciprofloxacin (n = 20):** 3 drops topical ciprofloxacin 250 μg/mL in saline solution locally twice a day until cure or up to 10 days
- **Oral ciprofloxacin (n = 20):** oral ciprofloxacin 250 mg twice a day until cure or up to 10 days

All interventions given for at least 5 days; those not cured at 5 days carried on up to 10 days

**Concurrent treatment:** not reported

**Outcomes**

**Outcomes of interest in the review:**
Primary outcomes:
• Resolution of ear discharge at 1 week (5 to 11 days) and 2 to 4 weeks (19 to 24 days). Unclear if otoscopically confirmed.

Secondary outcomes:
• Suspected ototoxicity (audiometric and vestibular function)
• Serious complications, including intracranial complications (such as otitic meningitis, lateral sinus thrombosis, and cerebellar abscess) and extracranial complications (such as mastoid abscess, postauricular fistula and facial palsy) and death
• Adverse effects from treatment

Funding sources
"The ciprofloxacin tablets and powder used in this study were kindly provided by Bayer Italia Spa, Milan, Italy."

Declarations of interest
No information provided

### Study characteristics

#### Methods

6-arm, open-label, parallel-group RCT, with 7-day duration of treatment and 10 days of follow-up; follow-up to 3 days after finishing the treatment

#### Participants

- **Location**: Spain

  **Setting of recruitment and treatment**: 3 ENT departments of 3 tertiary hospitals

  **Sample size**: 300 patients

  - **Number randomised**: 50 in each group
  - **Number completed**: 50 in each group

  **Participant (baseline) characteristics**:

  - Age (mean, range): 5 to 73, n = 36 (12%) were children (< 14 years)
  - Gender (F/M): 134 (44.7%)/166 (55.3%)
Cochrane Database of Systematic Reviews

Ramos 2003 (Continued)

- Main diagnosis: chronic ear discharge, which comprised the following groups:
  * Simple chronic otitis media (n = 128): no lesions of the ossicular chain, erosion of the tympanic frame, absence of tympanosclerosis and no evidence of cholesteatoma
  * Chronic otitis media with osteolysis (OMCO) (n = 57): osteolytic lesions and alterations of the mucosa of medium type, types of pansclerosis, granulomatous lesions, atelectasis or marginal perforation, without signs of cholesteatoma
  * Chronic cholesteatoma (n = 42): signs of infection of middle cholesteatoma
  * Chronic otorrhoea in operated ears (n = 73): radical mastoidectomy (n = 40), tympanoplasty infection (n = 21), transtympanic grommets (n = 12)

- High-risk population:
  * Cleft palate (or other craniofacial malformation): not reported
  * Down syndrome: not reported
  * Indigenous groups (Australian Aboriginals/Greenland natives): not reported
  * Immunocompromised: not reported

- Diagnosis method:
  * Confirmation of perforated tympanic membrane: all had otoscopic examination at baseline; 62.3% had perforation confirmed (marginal perforation: 1.43% non-marginal perforation: 42% attic perforation)
  * Presence of mucopurulent discharge: otoscopic examination
  * Duration of symptoms (discharge): “for more than 6 weeks or sporadically with 3 or more episodes in the last year”

- Other important effect modifiers
  * Alternative diagnosis of ear discharge: cholesteatoma (n = 42)
  * Number who have previously had grommets inserted: 12
  * Number who have had previous ear surgery: 73
  * Number who had previous antibiotic treatment for CSOM: 65.6% (n = 197)

Inclusion criteria:

- Chronic otorrhoea, meaning that those cases presenting permanent, unilateral or bilateral, otorrhoea for more than 6 weeks, or sporadically, as long as it has manifested 3 or more episodes in the last year, regardless of the origin and morphological changes

Exclusion criteria:

- Pregnant women
- Patients with renal and/or hepatic impairment patients who had undergone topical or systemic antibiotic treatment during the 48 hours prior to the start of the study
- Patients with mycotic infections
- Patients who had concomitant treatment with theophylline or antacids, which include magnesium hydroxide or aluminium hydroxide in the formulation

<table>

</table>

Concurrent treatment: not reported

Outcomes of interest in the review:
## Ramos 2003 (Continued)

**Primary outcome:**
- Resolution of ear discharge ("dry ear"), unclear whether otoscopically confirmed, at 1 to 2 weeks

**Secondary outcomes:**
- Hearing: hearing tests at time of diagnosis, at 8 days and at 15 days
- Suspected ototoxicity
  - Suspected ototoxicity: diagnosed with audiogram (specific definition not stated, but study reports 0/125 patients had ototoxicity from treatment)
  - Balance problems/dizziness/vertigo: not reported
  - Tinnitus: not reported

### Funding sources

### Risk of bias

<table>
<thead>
<tr>
<th>Bias</th>
<th>Authors' judgement</th>
<th>Support for judgement</th>
</tr>
</thead>
</table>
| Random sequence generation (selection bias) | Unclear risk       | Quote: "patients were randomly allocated into 6 groups"
|                                          |                    | Comment: insufficient information about the sequence generation. In addition, the study stated that children were not randomised to oral ciprofloxacin: unclear how this was done. |
| Allocation concealment (selection bias)  | Unclear risk       | Quote: "patients were randomly allocated into 6 groups"
|                                          |                    | Comment: insufficient information about allocation concealment. There is no information about how they maintained allocation concealment but did not randomise children to ciprofloxacin. |
| Blinding of participants and personnel (performance bias) All outcomes | High risk          | Comment: no information provided about blinding method or use of placebo. The treatment arms involved different dosage forms (oral versus ear drops) – blinding of these interventions is impossible without the use of placebo. |
| Blinding of outcome assessment (detection bias) All outcomes | High risk          | Comment: no information provided regarding who assessed the outcomes. For subjective outcomes (otoscopy examinations) the knowledge of treatment group may influence the results. |
| Incomplete outcome data (attrition bias) All outcomes | Low risk           | Comment: 2 patients on oral treatment were reported as withdrawn due to gastrointestinal adverse events. Unclear from which group this was and whether these patients were counted in the percentages reported. The percentage of withdrawal is small. |
| Selective reporting (reporting bias)     | Unclear risk       | Comment: audiogram was performed at baseline and end of treatment, but not reported |

## Yuen 1994

### Study characteristics
Yuen 1994 (Continued)

Methods

Non-blinded, parallel-group RCT, with 1 week of treatment and a total of 2 weeks follow-up

Participants

Location: Hong Kong, 1 site

Setting of recruitment and treatment: outpatient clinic of the Otorhinolaryngology Unit, the University of Hong Kong, Queen Mary Hospital between October 1991 and February 1993

Sample size: 60

- Number randomised: 30 in ofloxacin group, 30 in amoxicillin-clavulanic acid group
- Number completed: 29 in ofloxacin group, 27 in amoxicillin-clavulanic acid group

Participant (baseline) characteristics:

- Age: 18 to 70 years with a median of 35 years
- Gender (F/M): 33 (55%)/23 (45%)
- Main diagnosis: active chronic suppurative otitis media with central perforation
- High-risk population:
  - Cleft palate (or other craniofacial malformation): not reported
  - Down syndrome: not reported
  - Indigenous groups (Australian Aboriginals/Greenland natives): not reported
  - Immunocompromised: not reported
- Diagnosis method:
  - Confirmation of perforated tympanic membrane: size of perforation documented
  - Presence of mucopurulent discharge: 39/60
  - Duration of symptoms (discharge): not reported
- Other important effect modifiers:
  - Alternative diagnosis of ear discharge: none
  - Number who have previously had grommets inserted: none
  - Number who have had previous ear surgery: not reported
  - Number who had previous antibiotic treatment for CSOM: not reported

Inclusion criteria:

- Active chronic suppurative otitis media with central perforation

Exclusion criteria:

- Cholesteatoma
- Discharging mastoid cavity
- Large aural polyp
- Acute traumatic perforation
- Acute otitis media
- Presence of a grommet
- History of radiotherapy of temporal bone and otomycosis
- All patients had no prior antibiotic treatment for at least 1 week before commencement of treatment

Interventions

Intervention (n = 30): 0.3% ofloxacin ear drops 3 times daily for 1 week

Comparator group (n = 30): oral amoxicillin-clavulanic acid (375 mg) 3 times daily for 1 week

Concurrent treatment: suction clearance of aural pus under microscopy (conducted after obtaining microbiology sample at baseline)

Outcomes

Outcomes of interest in the review:

Primary outcomes:

- Complete resolution of ear discharge, measured at between 1 to 2 weeks
Yuen 1994 (Continued)

- Pain (otalgia)

**Secondary outcomes:**
- Hearing loss (pure-tone audiograms were carried out before commencement and after completion of treatment)
- Suspected ototoxicity (tinnitus, hearing loss, dizziness)

**Funding sources**
"This study was supported in part by a grant (No. 335/048/0040) from the committee on research and conference grants of the University of Hong Kong."

**Declarations of interest**
No information provided

**Notes**
- **Unit of randomisation:** person

AOM: acute otitis media; COM: chronic otitis media; CSOM: chronic suppurative otitis media; OME: otitis media with effusion; RCT: randomised controlled trial
For CSOM-1 to -7 Cochrane Reviews see Table 1.

Characteristics of studies awaiting classification [ordered by study ID]

Mehboob 2019

Methods

- 3-arm, unclear blinding, single-centre, parallel-group, unclear if RCT, with unclear duration of treatment and unclear duration of follow-up

Participants

- **Location:** Pakistan, 1 site

  - **Setting of recruitment and treatment:** ENT department of tertiary health care hospital in Karachi, May to September 2018

  - **Sample size:** 120 participants (120 ears)
Mehboob 2019 (Continued)

- **Number randomised**: 40 treated with ciprofloxacin, 40 treated with amoxicillin-clavulanic acid, 40 untreated (control)
- **Number completed**: not reported

**Participant (baseline) characteristics:**

- Age: range 18 to 75 years (inclusion criteria)
- Gender (F/M): 60 female (50%)/60 male (50%)
- Main diagnosis: unilateral ear presentation of chronic suppurative otitis media
- High-risk population:
  * Cleft palate (or other craniofacial malformation): not reported
  * Down syndrome: not reported
  * Indigenous groups (Australian Aboriginals/Greenland natives): not reported
  * Immunocompromised: not reported
- Diagnosis method:
  * Confirmation of perforated tympanic membrane: not reported, otoscopy confirmed
  * Presence of mucopurulent discharge: without fluid discharge at time of pure-tone audiometry
  * Duration of symptoms (discharge): not reported
- Other important effect modifiers:
  * Alternative diagnosis of ear discharge: not reported
  * Number who have previously had grommets inserted: not reported
  * Number who have had previous ear surgery: not reported
  * Number who had previous antibiotic treatment for CSOM: not reported

**Inclusion criteria:**

- Patients aged between 18 to 75 years
- Both the genders
- Unilateral ear presentation of CSOM without fluid discharge at the time of pure-tone audiometry

**Exclusion criteria:**

- Paediatric population
- Patients over 75 years
- History of neurological disorder or profound psychological distress, cardiac arrest, family history of sensorineural hearing loss or using hearing aid

<table>

<tr>
<th>Interventions</th>
<th>Intervention (n = 40 participants): ciprofloxacin, method of administration not reported, dosage not reported, duration of treatment not reported</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Intervention (n = 40 participants): amoxicillin-clavulanic acid, method of administration not reported, dosage not reported, duration of treatment not reported</td>
</tr>
<tr>
<td>Comparator group (n = 40 participants): untreated</td>
<td></td>
</tr>
<tr>
<td>Concurrent treatment: not reported</td>
<td></td>
</tr>
</tbody>
</table>

**Outcomes**

**Outcomes of interest in the review:**

**Primary outcomes:**

- Not reported

**Secondary outcomes:**

- Hearing: pure-tone audiometry was examined at different frequencies using an audiometer with aural headphones to measure hearing thresholds

**Notes**

**Funding sources**: "University Research funding committee of JSMU"
### Mehboob 2019 (Continued)

**Unit of randomisation:** person

**Methods for reporting outcomes of patients with bilateral disease:** not reported, only included unilateral presentation of CSOM

Hearing thresholds divided into 7 categories as normal (25 dB), mild (26 to 34 dB) hearing loss (HL), moderate (50 to 64 dB) HL, severe (65 to 79 dB) HL, profound (80 to 94 dB) HL and deaf

**Objective:** to study the correlation of hearing loss with depression, anxiety and stress in patients suffering from chronic supplicative otitis media in local population of Pakistan

Depression, anxiety and stress were scored taking depression, anxiety and stress scale (DASS) as tool and Likert scale was taken for scoring

Awaiting author reply regarding randomisation

### Samarei 2014

**Methods**

2-arm, non-blinded, single-centre, parallel-group "RCT", with 10 to 17 days duration of treatment and 30 days duration of follow-up

**Participants**

**Location:** Iran, 1 site

**Setting of recruitment and treatment:** not reported

**Sample size:**

- **Number randomised:** unclear – it appears some patients may have been excluded from the study
- **Number completed:** 40 in topical ciprofloxacin, 32 in systemic ciprofloxacin

**Participant (baseline) characteristics:**

- **Age:** not reported
- **Gender (F/M):** not reported
- **Main diagnosis:** purulent active otorrhoea and perforated tympanic membrane for more than 3 months
- **High-risk population:** unclear
  - Cleft palate (or other craniofacial malformation): not reported
  - Down syndrome: not reported
  - Indigenous groups (Australian Aboriginals/Greenland natives): not reported
  - Immunocompromised: not reported
- **Diagnosis method:**
  - Confirmation of perforated tympanic membrane: unclear (no method described but inclusion criteria implies all patients had perforated membrane)
  - Presence of mucopurulent discharge: unclear (no method described but inclusion criteria implies all patients had purulent discharge)
  - Duration of symptoms (discharge): 3 months (inclusion criteria)
- **Other important effect modifiers:**
  - Alternative diagnosis of ear discharge: 0%
  - Number who have previously had grommets inserted: not reported
  - Number who have had previous ear surgery: not reported
  - Number who had previous antibiotic treatment for CSOM: not reported

**Inclusion criteria:**

- Purulent active otorrhoea and perforated tympanic membrane for more than 3 months
Interventions

**Intervention (n = 40):** ciprofloxacin ear drops, unclear concentration, 2 drops twice daily, 10 days treatment and additional 7 days if ear not dry at 10 days

**Comparator group (n = 32):** ciprofloxacin orally 500 mg, 1 tablet twice daily, 10 days treatment and additional 7 days if ear not dry at 10 days

**Concurrent treatment:** “regular suction for outer middle ear washings.” No other concurrent treatment mentioned.

Outcomes

**Outcomes of interest in the review:**

**Primary outcomes:**

- Adverse effects (reported as measured in the methods but no results given)

**Secondary outcomes:**

- Hearing loss (measured as change in hearing threshold from baseline or at endpoint)
- Adverse effects from treatment (reported as measured in the methods but no results given)

Notes

**Unit of randomisation:** person

**Methods for including patients with bilateral disease:** not reported

Awaiting author reply regarding randomisation

CSOM: chronic suppurative otitis media; F: female; M: male; RCT: randomised controlled trial

[How was this diagnosed?]

Multiple serious complications
[How was this diagnosed?]

Comment/additional notes:
If any calculations are needed to arrive at the data above, note this down here.

1State briefly how this was measured in the study, especially whether there was deviation from what was expected in the protocol.
For adverse events, note down how these were collected, e.g. whether the adverse event was one of the prespecified events that the study planned to collect, when it was collected and how/who measured it (e.g. as reported by patients, during examination and whether any scoring system was used).

HISTORY

Protocol first published: Issue 6, 2018
Review first published: Issue 2, 2021

CONTRIBUTIONS OF AUTHORS

Lee Yee Chong: scoped the review, and designed and wrote the protocol. Screened the search results and selected studies, carried out data extraction, 'Risk of bias' assessment and statistical analyses, reviewed, wrote and edited the text of the review.
Karen Head: scoped the review, and designed and wrote the protocol. Screened the search results and selected studies, carried out data extraction, 'Risk of bias' assessment and statistical analyses, reviewed and edited the text of the review.
Katie Webster: screened the search results and selected studies, carried out data extraction, 'Risk of bias' assessment and statistical analyses, reviewed and edited the text of the review.
Jessica Daw: screened the search results and selected studies, carried out data extraction, 'Risk of bias' assessment and statistical analyses, reviewed and edited the text of the review.
Peter C Richmond: clinical guidance at all stages of the review, reviewed the analyses and reviewed and edited the text of the review.
Tom Snelling: clinical guidance at all stages of the review, reviewed the analyses and reviewed and edited the text of the review.
Mahmood F Bhutta: helped to scope, design and write the protocol, reviewed the analyses and provided clinical guidance at all stages of the review. Reviewed and edited the text of the review.
Anne GM Schilder: clinical guidance at all stages of the review, reviewed the analyses and reviewed and edited the text of the review.
Martin J Burton: clinical guidance at all stages of the review, reviewed the analyses and reviewed and edited the text of the review. Wrote the abstract for the review.
Christopher G Brennan-Jones: helped to scope, design and write the protocol, reviewed the analyses, provided clinical guidance at all stages of the review, reviewed and wrote the discussion and edited the text of the review.

DECLARATIONS OF INTEREST

Lee Yee Chong: none known.
Karen Head: none known.
Katie Webster: none known.
Jessica Daw: none known.
Peter Richmond: none known.
Tom Snelling: none known.
Anne GM Schilder: Professor Anne Schilder was joint Co-ordinating Editor of Cochrane ENT until April 2020, but had no role in the editorial process for this review. Her evidENT team at UCL is supported by the National Institute of Health Research (NIHR) University College London Hospitals (UCLH) Biomedical Research Centre (BRC), with research being funded by the NIHR, Wellcome Trust and EU Horizon2020. She is the National Specialty Lead for the NIHR Clinical Research Network ENT and Surgical Specialty Lead for ENT for the Royal College of Surgeons of England’s Clinical Research Initiative. In her role as director of the NIHR UCLH BRC Deafness and Hearing Problems Theme, she acts as an advisor on clinical trial design and delivery to a range of biotech companies in the hearing field.
Martin J Burton: Professor Martin Burton is joint Co-ordinating Editor of Cochrane ENT, but had no role in the editorial process for this review.
Christopher G Brennan-Jones: Dr Brennan-Jones's research team is primarily funded by the Australian NHMRC and the WA Department of Health. He sits on the national Technical Advisory Group responsible for developing treatment guidelines for otitis media in Australia.
