ABSTRACT

Background Individual behaviour changes, such as hand hygiene and physical distancing, are required on a population scale to reduce transmission of infectious diseases such as COVID-19. However, little is known about effective methods of communicating risk reducing information, and how populations might respond.

Objective To synthesise evidence relating to what (1) characterises effective public health messages for managing risk and preventing infectious disease and (2) influences people’s responses to messages.

Design A rapid systematic review was conducted.

Data sources Electronic databases were searched: Ovid Medline, Ovid PsycINFO and HealthEvidence.org, and grey literature (PreprintXiv, OSF Preprints) up to May 2020.

Study selection All study designs that (1) evaluated public health messaging interventions targeted at adults and (2) concerned a communicable disease spread via primary route of transmission of respiratory and/or touch were included. Outcomes included preventative behaviours, perceptions/awareness and intentions. Non-English language papers were excluded.

Synthesis Due to high heterogeneity studies were synthesised narratively focusing on determinants of intentions in the absence of measured adherence/preventative behaviours. Themes were developed independently by two researchers and discussed within team to reach consensus. Recommendations were translated from narrative synthesis to provide evidence-based methods in providing effective messaging.

Results Sixty-eight eligible papers were identified. Characteristics of effective messaging include delivery by credible sources, community engagement, increasing awareness/knowledge, mapping to stage of pandemic. To influence intent effectively, public health messages need to be acceptable, increase understanding/perceptions of health threat and perceived susceptibility.

Strengths and limitations of this study

- While we conducted a rapid review, we ensured that we completed it in a systematic manner with a broad initial search (eg, no restriction on study design) to develop recommendations from lessons in risk communication that we can translate to the current pandemic.
- The rapid review included all study designs with high heterogeneity, some of which were low quality, so findings should be interpreted tentatively.
- The focus of most of the studies included in the review was on determinants of intention and not behaviour, therefore we acknowledge that the recommendations may not lead to successful enactment of target behaviours (eg, hand washing) even though they may be helpful in increasing intentions.
- We were unable to conduct backward and forward citation searching on the included studies, this may have resulted in relevant literature not being captured.
- We had strong stakeholder engagement as part of the team with different expertise of behaviour science and public health that provided feedback from initial design through to development of recommendations to be used by public health practitioners.

Discussion There are four key recommendations: (1) engage communities in development of messaging, (2) address uncertainty immediately and with transparency, (3) focus on unifying messages from sources and (4) frame messages aimed at increasing understanding, social responsibility and personal control. Embedding principles of behavioural science into public health messaging is an important step towards more effective health-risk communication during epidemics/pandemics.
BACKGROUND

The outbreak of novel infectious diseases, including COVID-19, requires rapid changes to existing (eg, related to physical distance) and new (eg, use of face coverings) behaviours in the context of uncertainties and often rapidly evolving new knowledge. Public health messaging is one component of effective risk communication strategies to ensure sustained population level behaviour change. However, little is known about what characterises effective public health messages for dealing with infectious diseases and what factors influence the public’s response. 

Drawing from the behaviour change wheel (BCW) system for intervention development, the ‘COM-B’ model of behaviour change proposes that public health messages should be designed as multicomponent strategies to support people’s capability (the knowledge/skills), opportunity (societal norms/physical resources) and motivation (the desire/habit) to act; factors at the heart of the BCW. This theory has been used in current guidance to highlight core considerations for reducing the spread of COVID-19, namely, increasing knowledge of personal protective behaviours (capability), signposting and making available resources (opportunity), and explaining why behaviour change is important, while mitigating emotional reactions (motivation).

When building public health campaigns or interventions, it is important to consider past evidence to build a behavioural diagnosis using COM-B: accepted modes of delivery; and an evaluation of outcomes. It is crucial to understand public health messaging in rapidly changing epidemics/pandemics and for this, a review of the evidence base is needed.

Review aims

To conduct a rapid systematic review and to identify and synthesise evidence in order to provide evidence-based recommendations for designing and delivering public health messages for health authorities and social care organisations dealing with infectious disease outbreaks. This review aims to identify:

1. What influences people’s responses to public health messages about health-risk communication.
2. What characterises effective public health messages for managing risk and preventing disease during epidemics/pandemics.

METHODS

Rapid systematic review methods searches started in May 2020 and analysis was completed in July 2020. Public health messages were characterised as messages delivered by mobile technology, news broadcasts/newspapers, posters, leaflets and press conferences.

Information sources

The following databases were searched: Ovid PsycINFO, Ovid MEDLINE, PsYArXiv, OSF Preprints and healththevidence.org (search strategies are presented in online supplemental appendix 1). The protocol for this rapid systematic review is published on Prospero CRD42018188704. The SPICE criteria (Setting, Perspective, Phenomena of Interest, Comparison, Evaluation, Time Scope) was used to guide data extraction. Our search strategy was piloted with a scoping review to ensure that the terms were capturing all relevant literature and to also choose which databases to search. These terms were then shared within the team and with public health practitioners and behaviour science experts for feedback using an iterative process to finalise our search terms.

Patient and public involvement

This work was a rapid response to a request by Public Health Practitioners to the Health Psychology Exchange consortium. The Patient Public Involvement and Engagement Group within the Health Psychology Exchange group was consulted when developing the protocol.

Eligibility criteria

All study designs were considered for inclusion (eg, systematic reviews, empirical studies) and grey literature (eg, guidelines, frameworks, and policy documents) with no date restrictions until 20 May 2020. 

Papers were included if they:

1. evaluated a public health messaging intervention targeted at adults aged 18 years and above (no limitations on population or region),
2. concerned a communicable disease spread via primary route of transmission of respiratory and/or touch (human to human contact),
3. were written in English.

Papers on HIV were excluded as they involved different preventative behaviours and therefore deemed to be out of scope of the review. Papers that focused exclusively on public health messaging for vaccination uptake (intentions and uptake) during epidemics/pandemics were noted and the findings synthesised in a separate review.

To ensure that a broad range of literature, relating to epidemics/pandemics/health crisis communication, could be captured studies were not excluded based on outcome. However, outcomes of interest included preventative behaviours (eg, hand washing, quarantining), perceptions (eg, risk), intent and awareness.

Study selection

Titles/abstracts (80% double screened) and full texts were screened by 15 authors (figure 1; for further breakdown of the included studies see online supplemental appendix 2 in online supplemental materials). Conflicts over inclusion (2.3% had disagreements) were resolved through discussions with four authors (online supplemental appendix 3 provides detail on each author’s roles in screening, extraction and synthesis).

Data extraction

Characteristics of the papers (eg, type of message, quality of study), the type of health risk and results were extracted (online supplemental appendix 4). Four authors (JW,
SS, NC and DS) screened and completed a data quality check using Mixed-Methods Appraisal Tool6 for the 54 individual papers, the 11 preprints and AMSTAR7 for the systematic reviews (online supplemental appendix 5). Overall, there was a moderate agreement level between the reviewers with 61% level of agreement. Disagreements were resolved through discussion with moderators.

**Synthesis of results**

A narrative synthesis was conducted8 to identify key themes with respect to: (1) what influenced people’s responses to public health messages in general and for subpopulations in particular during salient time points (further details are presented in online supplemental appendix 6) and (2) interpreted recommendations for effective public health messaging for managing risk and preventing disease during epidemics/pandemics, which are presented below. The synthesis involved combining the results of reviews and individual studies reporting (1) qualitative studies, (2) quantitative studies and (3) both qualitative and quantitative studies, in order to describe the recommendations for effective delivery of public health messages. These were exported into NVivo (V.12) to data manage the combined results of different papers. To establish trustworthiness in data analysis, discussions among several members of the study team were held at fortnightly intervals to develop the coding framework, and to discuss, refine, and group the emerging codes into overall explanatory themes. All study authors were involved in establishing the conceptual framework.

**RESULTS**

A total of 68 papers rated as high-to-moderate quality (about 50% of them scoring as high quality and 32% of moderate quality) were included: 3 systematic reviews, 54 individual peer-reviewed papers and 11 preprints. The papers focused mainly on Influenza A virus subtype H1N1 (n=20), COVID-19 (n=15) and Ebola (n=11) and other diseases (n=12) which have emerged at different time points in the last 50 years. The timelines from initial outbreaks are highlighted in figure 2. The included studies were conducted at various time points (eg, beginning, during or post) during these pandemics and 11 did not report the timing (online supplemental appendix 6). Key variables included (1) behaviours (eg, hand washing, quarantine, using tissues, physical distancing), (2) cognitive factors (eg, increase in awareness, perceived risk) and (3) emotions (worry, anxiety) (see online supplemental appendix 5 for full characteristics of papers).

A narrative analysis of the papers was conducted on what was mostly qualitative work that reported on determinants of intent to adhere to guidelines. These were organised according to preconceptions and understanding of the threat, perceived susceptibility and perceived risk severity (threat appraisal). This narrative analysis is presented in online supplemental appendix 5.

**Figure 1** Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) diagram.

6. Across the different themes and subthemes developed about community engagement, messages for subpopulations, increasing trust, perceptions and understanding of threat and threat appraisal, we developed four areas of recommendations to provide evidence-based steps to be taken to provide effective public health messaging during pandemics/epidemics. These recommendations are cross-referenced to the narrative synthesis in table 1 and the recommendations are reported below with evidence summarised.

### Recommendations

Four recommendations were derived from the evidence (see online supplemental appendix 6 for a comprehensive report of the evidence on influences on effective public health messaging, messages for subpopulations...
and communication at salient points in an epidemic/pandemic). Results were synthesised in figure 3, including the recommendations and influences on behaviours. The recommendations are (1) engaging with different communities, (2) addressing uncertainty immediately, with transparency, (3) unified messaging and (4) message framing.

(1) Engaging with key stakeholders and communities
(1a) Involve community leaders and others perceived as credible sources within the community

One high-quality study indicated that messages designed without input from the target population may lead to low levels of public adherence to behaviour change messages. A moderate-quality review found that this is especially important when dealing with inconsistencies and changing information. A high-quality systematic review found that the public pay more attention to messages if the community is engaged in its development as this will ensure that the information is relatable, and addresses the concerns, values, interests and priorities of the community. Consequently, this may lead to heightened perceptions of personal risk. Two studies of low-to-moderate quality, suggested that one way to do so is to include community leaders, to find people who are trusted and allow faith-based organisations to help. One moderate-quality study found that culturally and linguistically appropriate messages (eg, delivered via video clips) can also help retain long-term knowledge of preventative behaviours.

A preprint study stated that over time preferred expert sources (eg, government websites) are displaced by unofficial sources (eg, social media) for information regarding epidemic/pandemics; therefore, developing ties within the community (eg, trusted spokesperson) can be helpful to provide accurate information. A high-quality study found that students tend to perceive information from their university (from their own communities) as more credible than the media. One low-quality study found that community engagement is also important for quickly disseminating messages which are translated into different languages.

(1b) Tailoring helps to make the key messages applicable to an individual’s situation

A high-quality systematic review found that those who are less likely to accept that they are at personal risk of the threat (eg, the young, least educated and hard to engage communities) are also less likely to adhere to the recommended behaviours. This has important implications for reducing inequalities through tailored public health messaging. Social networks and having close ties to the community are drivers of better knowledge and behaviour change. Partnership with community leaders and/or community organisations should be used to reach out to the most vulnerable (this may include those who have a disability for example, hearing/vision) and those who are least literate as well as non-Native speakers.

Individuals desire information that fits with their experiences. Studies of moderate quality have shown that adaptable and personalised information, that is context-driven, is more effective in changing determinants of behaviour, especially in vulnerable groups. One moderate-quality study and two high-quality studies showed that messages should be tailored to take into account: (1) different levels of perceived susceptibility (eg, younger adults see themselves as less vulnerable than older adults); (2) likelihood of misunderstanding instructions (eg, older people thought a campaign was referring to handkerchiefs rather than disposable tissues); and (3) skills needed to enact the behaviour (eg, migrant workers did not know how to wear a face covering). One low-quality study found that there may be differences in message preferences (eg, older adults and mothers preferred messages that emphasised the protection of others).

(1c) Consider any difficulties accessing information and levels of literacy

Messages are typically delivered at a high literacy level. When individuals do not understand the message, they may engage in behaviours that reflect their understanding. Some target groups, such as those with low literacy levels, could particularly benefit from a simplified, clear and consistent message. Pilot-testing messages can help identify phrasing that can be confusing or unfamiliar.

It is also important to ensure public health messages reach non-native speakers by using translated materials as shown in a high-quality study. Older people in non-native groups in particular may not understand English. Thus, messages should be communicated in the original languages and through generations. Translated information should be disseminated through culturally appropriate channels such as community visits, town hall meetings and health and education and communication channels to complement mass media messages. This reinforces the need for community leaders (recommendation 1a) in aiding with translations and identifying the appropriate channels.

Some people have limited experiences of engaging in recommended behaviours (eg, using face coverings or a thermometer). These limited experiences highlight a need for training/skill development to be included as part of a public health campaign. This will improve health literacy and self-efficacy, especially when it refers to ‘new’ behaviours. Including training/skill development fits in with taking a COM-B model approach in developing public health messaging as it increases an individual’s physical/psychological capabilities. Benefits to taking this approach could be enhanced with equally improving motivation (reflective and automatic) by considering other recommendations (eg, recommendation 4: message framing) as well as considering opportunity for behaviour (social and physical) which can identify potential barriers (eg, social norms).
Message delivery should be appropriate for the targeted population. For example, two studies of moderate-to-high quality suggested that social media can reach younger people. A study of moderate-quality showed that social media can be effective in communicating messages fostering trust and providing opportunities for dialogue. However, as highlighted in two studies of high quality, there are disadvantages as (1) social media is also associated with misconceptions, such as what causes the disease and (2) those without internet access (or a device) would be excluded. A high-quality study found that those of lower socioeconomic status (SES) were less likely to use a website, and more likely to find public health messages from TV and radio to be confusing and contradictory than those of higher SES. In specific situations for example, messages through the use of posters in bathrooms to increase hand washing need to not just have prompts for the behaviour but also messages about transmission as a high-quality study found that prompts alone do not increase hand washing. This is consistent with the Health Belief Model where cues of action can trigger behaviour but requires cognitive representations of perceived susceptibility and perceived barriers/costs to action.

(2) Addressing uncertainty immediately and with transparency

(2a) Address uncertainty and changing information that may exist during an ongoing public health crisis

Public health messages with emerging epidemics/pandemics are likely to involve much uncertainty about the virus and the appropriate preventative behaviours. A high-quality systematic review found that honest reporting about the threat, through a presentation of known and unknown factors, increases people’s knowledge and makes attitudes and beliefs more positive; it also increases trust in the way the government is handling the emergency.

As epidemics/pandemics develop the information and recommended behaviours may change. Changing information decreases trust in the government. However, three studies of moderate-to-high quality reported that prompt (ie, giving information as it happens), stage appropriate (ie, not seen as too lenient or too extreme for the risk level) and transparent messaging (ie, that includes recommended preventative behaviours) reduces anxiety around the reported health risk.

(2b) Consistency and co-ordination between different sources of information

Different sources of information may give information and behaviour change instructions that are inconsistent with each other, especially as knowledge rapidly changes over time. Differences in the information and behaviour change instructions between countries should be explained. Information should be transparent, not be hidden and predictions should not be too optimistic — this will increase overall trust towards authorities.

(2c) Be transparent: admit errors and unknowns whenever appropriate

A high-quality study showed that if uncertainties are not acknowledged or transparency is not provided, the consequences of the errors are addressed and this can reduce trust in agencies, thus reducing information acceptance and compliance with recommendations.

Two studies of moderate-to-high quality found that information needs to be released as early as possible at the start of the outbreak, whenever there is conflicting information and even if there are unknowns. Honest, open and explicit information, transparency and assurances of personal data safety are important especially when promoting preventative behaviours. A low-quality study found that if official sources report the outbreak before unofficial/informal sources, then they become the leading indicator that people use for their information. Delay can impact the public’s trust in official sources that leads to beliefs that the threat is exaggerated by government or news media and increases the chance of apathy and communication fatigue.

(2d) Be transparent: identify sources of information

Two high-quality studies reported that attempting to increase knowledge in the context of low levels of public trust in the source can make a message ineffective; and mistrust can increase if the perception is that the information is exaggerated or if the outbreak is perceived as uncontrolled. Three preprint studies reported that trust is key to the acceptance of messaging that can lead to behaviour change (eg, using masks, physical distance), thus there is greater adherence when the messages come from trusted sources.

Sources that potentially can be perceived as credible by the general population can include public health experts, organisations (eg, Centers for Disease Control and Prevention) and state and local governments. A study found that believability of messages was reduced by scepticism towards the media and governments; in these instances, the threat was perceived as exaggerated and able to cause unnecessary panic which could influence low adoption of recommended behaviours. Therefore, it is important to ensure transparency highlighting that information sources are credible and legitimate.

(3) Unified messages

(3a) Deliver consistent, clear, core messages about risk and preventative behaviour across sources within the same time points

Where possible, messages should be unified across sources; as shown by two high-quality studies, this is especially important for those groups who have lower literacy (eg, lower SES) as they are more likely to perceive messages as confusing and inconsistent. A moderate-quality review found that unifying messages result in a greater understanding of the health message, greater perceived risk and
clear guidelines for behaviour; these all contribute to increased trust. A high-quality study found that a repeated measures survey during the H1N1 pandemic, showed trust levels in the government decreased over time and this decrease was due to conflicting messages at concurrent time points. In two moderate-quality studies it was found that if messages from different sources provide clear, consistent instructions these are more likely to be recalled and adhered to. When messages provided the public with clear consistent information, while admitting that information is evolving, reported the risks, and focused on risk-reducing actions, people were more likely to perform protective behaviours (eg, clean objects, wash hands and use tissues when sneezing).

(3b) Identify inconsistencies in messages from uncontrolled sources, especially when addressing key preventative behaviours

While official sources of information (such as government sources, or public health bodies) are perceived as legitimate, individuals do not always find them useful as highlighted in one high-quality study and one moderate-quality study, and consequently seek other sources (eg, unofficial sources such as family or social media). In a moderate-quality study, it was found that individuals seek information from multiple sources to meet different information needs. Different unofficial sources of information may give information and behaviour change instructions that are inconsistent with each other and official sources. Additionally, as found in a high-quality study, unofficial sources may detract from understanding of preventative behaviours. It is important to acknowledge and address the inconsistencies in unofficial sources.

When addressing inconsistency, a high-quality study found that it is also important to recognise that some messages may appear inconsistent due to varying levels of personal risk of different groups (conditional messages). To improve clarity these conditional messages should be identified and where possible explained or dispelled.

(3c) Increase the public’s awareness of the risks of the virus to their own health and the health of others

Public health messaging that included information about the threat can be effective in identifying symptoms and changing behaviours. From six high-quality studies, it was found that the key aim of public health messages early in an epidemic/pandemic is typically to increase knowledge and awareness of the health–risk (see online supplemental appendix 6 for papers and priorities mapped onto time points). However, knowledge about the virus alone is not sufficient to change behaviour; acknowledgement of unknown factors, how to identify symptoms and how to prevent contracting and spreading the virus is also necessary as highlighted by five high-quality studies and a high-quality systematic review, two moderate-quality and one low-quality study. A low-quality study found that when perceived risk is low, ignoring recommended behaviours is rationalised.

(4) Message framing

(4a) Increase factual knowledge of all aspects of a virus (eg, symptoms) and benefits of preventative behaviour using an appropriate message frame

Six high-quality studies found that framing and choice of language are influential in how individuals understand the threat and in turn behave. Positively framed messages (emphasising the benefits of preventive behaviours) may be effective. For example, gain-framed signs (eg, ‘stay healthy this season. Sanitise your hands’) are more effective in influencing the use of hand sanitiser than signs that emphasised people’s susceptibility to contamination.

Non-narrative messages (ie, factual) are more effective than narrative messages (eg, story-telling such as a movie Contagion) in changing knowledge and perceived response efficacy related to prevention of influenza. Factual and scientific knowledge in messages in the media can positively influence risk perceptions. While formal information (presented from credible sources) increased understanding.

(4b) Consider framing messages around social responsibility and norms

Cohesive social networks and having close ties to the community are drivers of better knowledge and compliance with preventive measures. There is some moderate-quality evidence to suggest that framing messages about others’ risk, in addition to your own risk, is effective in increasing information seeking. In a high-quality systematic review, it was found that being worried (about self or family members at risk) was an important predictor of compliance with recommended preventative behaviours, such as using tissues, hand gel and washing hands. The effects of worry about others at risk on compliance with preventative behaviours can potentially be amplified when combined with messages about being socially responsible. A high-quality study found framing messages with positive social responsibility to be useful for the public.

The grey literature highlighted that developing prosocial messages and promoting positive emotional appeals, increased willingness to self-isolate especially when producing a strong, positive emotional response (such as fear). Prosocial framing is effective in changing behaviour; this may be due to inducing compassion, activating social norms, altruism or moral duties.

(4c) Choice of language needs to be clear and appropriate to understanding the magnitude of risk

A high-quality systematic review and a moderate-quality study found that messages should sufficiently increase worry and perceived severity of risk to self and others so as highlighted in a high-quality study, recommendations are seen as proportionate and behaviour change is more likely to occur. However, in two high-quality studies, it was found that inducing too much fear has mixed results on behaviour: it can be counterproductive if this leads to panic.
There can also be confusion about the use of technical terms. A high-quality study found that it is difficult to differentiate between pandemic influenza and seasonal influenza especially when symptoms are framed as ‘flu-like symptoms.’

(4d) Frame the message to emphasise positive beliefs about one’s own health and that preventative behaviour is within their control. A study of moderate quality found that when messages provided the public with clear consistent information (while admitting that information and evidence is evolving), focused on the practical actions that people can take to reduce their risk and emphasised the efficacy of those actions, people were more likely to perform preventative behaviours. This may also further empower them and help them become socially responsible as shown in a low-quality study. People are more likely to follow guidelines when there are fewer perceived barriers to perform recommended behaviours, when benefits are emphasised and when contextual factors (eg, anxiety about missed work) are addressed.

Recommendation of increasing self-efficacy through messaging is well supported in theoretical frameworks about behaviour change and risk communication for example, the Theory of Planned Behaviour, Health Belief Model, Protection Motivation Theory, the Health Action Process Approach, COM-B model and Social Cognitive Theory. Increasing self-efficacy has positive implications on planning, intention and then possibly behaviour. This review includes limited but high-quality evidence that people want messages about specific actions that they could take to protect themselves and their families during the epidemic/pandemic with messages that emphasise the benefits of prevention behaviours (positively framed) potentially effective in increasing uptake and compliance. Informing the individual regarding preventative actions to stop the spread of the disease is particularly important in the early stages when the message is understood, different populations have different barriers to address in order to change behaviour. A COM-B behavioural diagnosis can help to inform public health strategies (eg, lower SES groups find costs of face coverings a barrier) as suggested in recent British Psychological Society guidance (see online supplemental appendix 7 for how current recommendations map onto the guidance). Our review suggests that unified messaging can increase trust, build community resilience and increase perceived risk and knowledge of threat. Furthermore, consistent messaging through different time points during an evolving pandemic are important to consider for context-specific recommendations; these were rarely considered or reported in the studies included in the review.

We found evidence of mode of delivery as an important consideration of public health messaging. Specifically, there should be careful consideration of how to communicate public health messages, which should target specific populations. For example, making use of social media platforms to target younger populations, or the radio as a delivery method for older populations. Translations for different cultures, and the inclusion of community leaders as part of public health message campaigns, should also be prioritised. This would ensure that all populations are reached (and not stigmatised), and the knowledge, concerns, cultural values, interests and priorities of the targeted populations are all considered. However, as noted in one of the studies this can be very difficult when an in-house translation service does not exist, and the rapidly evolving scientific evidence will challenge the turnaround time for developing, translating and disseminating information.

**Limitations**

We acknowledge the present rapid systematic review has limitations. Although we searched multiple databases systematically it is possible that relevant research was excluded from this review since we did not have the resources to translate non-English language papers in such a short space of time or conduct backward and forward citation searching. The inclusion of unpublished literature in the review means some findings may change once these papers have been published in peer-reviewed journals. However, our inclusive approach means a range of types of messages and a variety of factors related to what influences public perceptions of messages have been identified and used to inform recommendations for messaging during current and future epidemic/pandemics.

The aim of this rapid review was to synthesise lessons learnt from previous epidemics/pandemics to provide evidence-based recommendations about what characteristics create effective messaging. The focus of most studies was on determinants of intent and not behaviour, which may have implications on successful enactment of target behaviours. As highlighted in theories (such as health action process approach), intention formation is
part of the process and key to planning and more work is needed to understand the translation into action. Inclusion of different infectious disease (although the messaging would be of similar behaviours) may have included different contextual influences that we could not account for when synthesising the data (e.g., different countries and different social norms or political influences). Furthermore, additional work is needed to understand the moderating effects of individual differences on message acceptance.

Much of our evidence is consistent with components of relevant health behaviour models (e.g., Protection Motivation Theory75, Health Action Process Approach76 and Health Belief Model14), with some studies reporting the use of the models in their design. These models state that people perform protective behaviours when they perceive (1) the threat as sufficiently threatening (i.e., they are vulnerable to a severe risk), (2) the recommended behaviours to be effective and (3) they have self-efficacy to perform the behaviour. We found evidence that such cognitive appraisals were important considerations for developing public health messages, but further research is needed to examine effects on behaviour change.

CONCLUSIONS

Increasing knowledge and awareness of health risks alone is unlikely to be sufficient to increase understanding of risk and subsequent risk reduction behaviours, and adherence to recommendations. Rather, taking a multifaceted approach to public health messaging which considers all relevant drivers of behaviour (social, psychological and environmental factors), is recommended. Our four key recommendations should be considered when designing and delivering public health messages: engage communities in the development of public health messaging, using credible and legitimate sources, address uncertainty immediately and with transparency, focus on unified messages from all sources and develop messages aimed at increasing understanding, inducing social responsibility and empowering personal control. These are being translated into practical guidelines for agencies. Embedding these principles of behavioural science into public health messaging is an important step towards more effective health-risk communication.

<tr>
<td>Avery (2009)</td>
<td>USA</td>
<td>Avian flu</td>
<td>Press releases issued by federal and global health agencies</td>
<td>Not reported</td>
<td>The threat was not localized; outlets for publics to contact for more information were not always present, and there was inconsistency in how avian flu was referenced. There was a steady increase in the volume of releases since 2004, and public health information officers generally seemed to recognize the importance of partnerships and timeliness in pandemic preparedness. Public health communicators must establish a strong sense of efficacy in an informed public to insure that audiences will adhere to protocol rather than succumb to hysteria in the face of a wide-scale crisis such as pandemic flu. They must also provide information accessible to all publics, including those who do not have Internet access.</td>
</tr>
<tr>
<td>Basnyat &amp; Lee (2014)</td>
<td>Singapore Qualitative</td>
<td>H1N1 pandemic</td>
<td>Singapore Ministry of Health press release in newspapers</td>
<td>N/A</td>
<td>The media did convey useful information for managing the pandemic from the Ministry of Health press release (i.e. social responsibility, benefits of lockdown) and these were often in the tone/semantics of colonial-era ideologies that are present within the culture in Singapore and reflect that of the government. Beneficial for the government to provide more than basic information, such as about coping with anxiety, and consider how other types of media (e.g. social media, blogs) can be used too.</td>
</tr>
<tr>
<td>Berry (2007)</td>
<td>Canada</td>
<td>SARS/other infectious diseases/general health</td>
<td>Media reports - newspaper, radio, television, and internet news on health-related topics</td>
<td>Not reported</td>
<td>The results of the content analysis showed that in 2003, there was far more information available in the news media on SARS and West Nile Virus than on other health topics with greater population prevalence, such as obesity or heart disease. The number of articles about SARS in 1 year was greater than for any other individual topic across all 5 years, with the exception of smoking (which in 2003 had only 36 articles, compared to SARS, which had 164) and “other” topics. Expert sources were cited far more often than nonexperts.</td>
</tr>
<tr>
<td>Bonwitt (2018)</td>
<td>Sierra Leone &amp; Guinea Longitudinal qualitative</td>
<td>Ebola</td>
<td>posters</td>
<td>Various preventative behaviours</td>
<td>All study participants, irrespective of age or gender, were aware of wild mammals acting as a source of transmission for Ebola virus disease (EVD); respondents gave a variety of answers when asked</td>
</tr>
</tbody>
</table>
what species of animal could transmit Ebola - this confusion may have rested in the content of public health messages, which were inconsistent in the species shown to be potentially hazardous; People simply refused to believe that wild meat could pose any health risk; Those that believed or partially believed in the link between EVD and wild meat adopted various strategies to mitigate the perceived risk of infection. Most admitted to only refraining from eating those animals that they understood as posing a risk for EVD; The widespread suspicion over the risks posed by wild animals prompted discussions during village meetings to discuss the veracity of public health messages. Rather than outright rejection of these messages, people elaborated situated hypotheses to make sense of the conflicting and incomplete information they had received. This process of contextualisation helped to bridge the disjuncture between fear and the highly routine nature of eating meat.

<th>Disease</th>
<th>Information Seeking Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cole &amp; Watkins (2015)</td>
<td>Liberia, Sierra Leone or Guinea</td>
<td>Interviews</td>
<td>Ebola</td>
<td>Information-seeking</td>
<td>Their recall can be grouped into three broad source categories (official, international and local media, and informal) Throughout later information-seeking behaviour, interviewees maintained a distinction between the three categories. This affected how they trusted and processed information from each, although generally they tended to use all three simultaneously. Multiple source information gathering, especially following up from informal information (personal experiences) because they felt that was more rumour and wanted confirmation from official sources but felt official sources were slow with the information. Consistency provided reassurance and helped to be trusted. perception of risk, triggered by hearing that someone they knew personally, or felt an affinity to, had contracted the virus. know who employees see as their community and ‘people like me’. Behavioural changes seemed to kick in at the border between the near and real at-risk rather than at the border between far at-risk and near at-risk. Those in the far at-risk group generally showed more concern for people they knew in higher risk categories than for themselves.</td>
</tr>
<tr>
<td>Crosier (2015)</td>
<td>UK, Italy, Hungary</td>
<td>Qualitative interviews</td>
<td>H1N1</td>
<td>Government poster and engagement</td>
<td>The study found a lack of planning and a low value attached to the skills required to produce effective communications. There was a dearth of good quality audience research to inform the development of communications. Little thought had been given to...</td>
</tr>
</tbody>
</table>
the tone, targeting or channelling of messages. Instead, communications were characterized by a ‘one size fits all’ and a ‘top down’, expert-led response. There was also little effort to evaluate the impact of communications, but where this was done, very low levels of public compliance and engagement with key behavioural messages were found.

<p>| Davis (2015) | Australia &amp; Scotland | Qualitative interviews and focus groups | H1N1 pandemic 2009 | Broadcast and electronic media | Hygiene (e.g. covering mouth when coughing or sneezing, washing hands, cleaning surfaces), social isolation, vaccination | Participants wanted information but to be able to interpret advice based on own situation. Information on hygiene and social isolation endorsed but seen as short-term solution as being social is a central part of life. Participants had an individualistic approach to risk, decide whether to adopt PH behaviours based on risk to themselves, gender norms play a part in understanding and engagement with hygiene and social isolation. |
| Freiman (2011) | USA | face to face interviews | H1N1 pandemic 2009 | TV, newspaper, internet, family/friends, workplace, radio, other | Reporting on a range of preventative behaviours | Variable - did not always have the desired effect, or an effect at all. relied on the internet - however a lot of the target population did not have access to this - and thus were missed. Even those with internet access were unlikely to visit the CDC’s website to learn about H1N1 |
| Gray (2012) | New Zealand | Focus groups | H1N1 pandemic 2009 | Ministry of Health campaigns | General protective behaviours | Four major themes: personal and community risk, building community strategies, responsibility and information sources. People wanted messages about specific actions that they could take to protect themselves and their families and to mitigate any consequences. They wanted transparent and factual communication where both good and bad news is conveyed by people who they could trust. |
| Holmes (2009) | Canada | Semi-structured interviews | crisis | Hypothetical | Risk perceptions | The notion of uncertainty – and the difficulties associated with communicating in uncertain situations – arose frequently. Recommendations: is to set and get agreement on a goal or goals (there may be different goals set for different audiences or specific situations). View all other aspects of communications planning and implementation through this ethical lens. Media representatives should be engaged immediately in discussions about a potential emerging infectious disease outbreak, including the role media should play and how the public health community can help them fulfil that role. Building trust with the public. |</p>

<td>Rim (2014)</td>
<td>USA</td>
<td>content analysis + correlating with survey results</td>
<td>H1N1</td>
<td>News media</td>
<td>Various</td>
<td>The more info from health authorities, the more news coverage. The same correlation for severity of content. Increased information subsidies with salience of the severity attribute was linked with increased H1N1 salience in media coverage. But no relationship between the severity attribute use in media coverage, and the public perception of risk. Framing that effectively empowers the public to engage in desired behaviour should be further studied for the success of a public health campaign.</td>
</tr>
<tr>
<td>Rimi (2016)</td>
<td>Bangladesh</td>
<td>ethnography</td>
<td>avian influenza</td>
<td>Posters</td>
<td>Prevention (handling poultry)</td>
<td>Incorporating non-health benefits might improve acting on recommendations. More people heard about the bird flu after the intervention, and had more awareness around the disease, as well as performed preventative behaviours. Not all behaviours changed in the desired direction though (e.g., selling sick poultry, separating it). Reported behaviours were not consistent with the observations done by the researchers though. People rationalised ignoring recommended behaviours - low perception of risk - the flu not present among their birds, also finance issues and not worrying about getting ill. Also inconvenience was mentioned, as well as social pressure not to follow the recommendations, and scepticism about the necessity of the intervention - some conspiracy theories.</td>

</tr>
<tr>
<td>Teasdale (2011)</td>
<td>UK</td>
<td>Focus groups</td>
<td>H1N1 pandemic</td>
<td>Government + author-developed messages</td>
<td>Government advice was stay at home if you have flu-like symptoms and continue to go to work if you do not (behaviour not tested in this study though)</td>
<td>Participants were sceptical about the feasibility and appropriateness of self-diagnosis of pandemic flu. Participants actively evaluated recommended actions according to their own beliefs and reasoning about flu and their perceptions of the costs of carrying out the recommended actions. For most people the experience of the H1N1 pandemic was relatively mild compared to previous influenza pandemics of the 20th century. Consequently, the recommendation to stay at home was perceived as inappropriate. Written government communications aiming to improve and maintain population health may also need to address the recipients' perspective. Attempts should be made to elicit and address common doubts and concerns, to reduce perceived barriers to recommended behaviours, emphasize benefits, to find ways to support people to adopt them and consider the likely contextual factors that may affect perceptions of the advice.</td>
</tr>
<tr>
<td>Tully (2019)</td>
<td>West Africa</td>
<td>Content analysis</td>
<td>Ebola</td>
<td>Hyperlinks - embedded content in social media, e.g. Twitter used for information dissemination.</td>
<td>Risk perceptions</td>
<td>Increased credibility and awareness of messages. Organizations produce proportionally fewer tweets than news outlets - maintaining an active Twitter presence allows response organisations to promote their work and position themselves centrally to the unfolding crisis and conversation. Results suggested that 'owned' and 'earned' media served as informational resources and promotional pieces for the organizations. Repeatedly linking to sites controlled by the organization and/or produced by news media and other reliable sources served as a low-cost way for organizations to keep pace with the rapid flow of information on social media.</td>

<tr>
<th>Prati (2011)</th>
<th>Italy</th>
<th>Cross-sectional survey</th>
<th>H1N1</th>
<th>Educational campaign</th>
<th>Various – all preventative behaviours</th>
</tr>
</thead>
</table>

Recommended behaviours such as cleaning objects, social distancing and washing hands were related to all the psychosocial factors except for trust in the institutional response to the outbreak and trust in medical science. Trust in medical science was significantly associated with cleaning objects. To use tissues when sneezing was predicted by all the psychosocial factors, except for trust in medical science and control. These results showed that media trust, trust in the Ministry of Health (regardless of what was done to reduce this risk), worry and perceived severity of illness predicted all the recommended behaviours. Exposure to the Topo Gigio campaign did have a limited influence on complying with health related recommendations but only with regard the use of tissues when sneezing.

<table>
<thead>
<tr>
<th>Rim (2014)</th>
<th>USA</th>
<th>content analysis + correlating with survey results</th>
<th>H1N1</th>
<th>News media</th>
<th>Various</th>
</tr>
</thead>
</table>

The more info from health authorities, the more news coverage. The same correlation for severity of content. Increased information subsidies with salience of the severity attribute was linked with increased H1N1 salience in media coverage. But no relationship between the severity attribute use in media coverage, and the public perception of risk.
Framing that effectively empowers the public to engage in desired behaviour should be further studied for the success of a public health campaign.

<tr>
<td>Updegraff (2011)</td>
<td>USA</td>
<td>Experimental design with 3 conditions</td>
<td>H1N1</td>
<td>Posters/ signs placed besides hand sanitizer units around university campus Use of hand sanitizer dispensers</td>
<td>All signs resulted in significantly greater usage than no sign, but they were not equally effective. Dispensers with the gain-framed signs had the greatest usage of all, with 66.4% more use than dispensers with no signs (p &lt; .001). Loss-framed signs were associated a 58.4% increase in use over no sign (p &lt; .001). The social norms signs (44.3% increase) and the perceived susceptibility signs (40.6% increase) were associated with somewhat lower increases in usage compared to the gain-framed and loss-framed signs, but both led to significantly more usage than no sign at all (both p’s &lt; .01). Gain-framed signs received 12.5% more usage than dispensers in the other sign conditions combined, a significant difference (p = .029). Usage of sanitizer dropped consistently over time, closely mirroring temporal trends in public interest in H1N1. This study showed that the relatively simple strategy of placing theoretically grounded cue-to-action reminder signs at the point-of-use significantly promoted usage. The worst-performing sign emphasized people’s susceptibility to contamination.</td>

</tbody>
</table>
= 49), and emotional responses such as fear and worry (47%, N = 43). Factors influencing the H1N1 vaccination acceptance rate (26%, N = 24) were also frequently investigated. Including trust in the way the government is handling the emergency. Consequently, there is some evidence that better knowledge and trust are likely to be associated with the adoption of recommended behaviours (i.e. immunization practices). Social networks and ties to the community are also drivers of better knowledge and compliance with preventive measures; these results suggest that non-traditional channels of communication (i.e. partnership with community leaders or organizations) should be used to reach out to the most vulnerable and those in need of a better understanding of the risks and actions needed to be able to protect themselves. Public health communication messages are still delivered at a literacy level that does not meet the needs of the less educated.

</tbody>
</table>

1. Providing more information is more effective than less information, 2. it always better to over-react than to under-react. 3. fear and ignorance of any disease is worse than the disease itself. It reduces all to impotence and defeat. Information is an all-powerful tool to fight fear. It empowers people and allows them to become socially responsible.

Technology (The Infrared Fever Screening System), a SARS-dedicated TV channel, transparency, leadership (highest levels of government came into the picture very early in the crisis and took the lead), communication tools (moderating public fear through dialogue with grassroots leaders and community, briefings for foreign business groups, diplomats, religious groups, trade associations, cartoons, hotlines, songs on TV), earning the trust and confidence of Singaporeans, rebuttal of negative reports in the foreign media claiming that foreign visitors had been infected with SARS whilst transiting Singapore, outbreak communications across cultures.

The forum wanted full and frank information about the potential risk and international developments including numbers of cases and fatalities. Forum members understood that predictions about the pandemic influenza were uncertain,
this did not lead to loss of confidence in the experts or the information they imparted. Third, the forum recommended releasing geographically localizing information about initial cases. The forum recommended increasing use of television and websites, including those targeting youth and rural and remote groups as the pandemic developed. The forum recommended immediate activities to educate and build awareness and swift action if and when Australia has its first cases of PI.

</table>
| Merkley, (2020) | Canada | 2-part online experimental survey study | COVID-19 | News stories relating to the pandemic - signalling information from experts or non-experts. | Information on hygiene (i.e. cleaning surfaces), social gatherings, testing and scientific discoveries. | Study 1: We find that our respondents were on average 3 points more likely to select news stories with headlines featuring experts (p~0.007). News stories with headlines featuring experts scored 2 points higher in credibility (p<0.002). In support of H1, we find that the effect of receiving headlines featuring experts is heterogeneous across levels of anti-intellectualism. The marginal effects on story selection are shown in the left panel of Figure 2. Respondents with the lowest levels of anti-intellectualism are six points more likely to select stories featuring experts (p<0.001), but this effect disappears once the mid-point of the scale is reached. 
Study 2: Our respondents were 19 points more likely to select COVID-19 news (p<0.001). They also viewed such news as 6 points more credible (p<0.001) and 19 points more important (p<0.001). Once again, |
anti-intellectualism strongly conditions news preferences. Respondents with the highest levels of trust in experts were 25 points more likely to select COVID-19 news \( (p<0.001) \), and viewed it as 8 points more credible \( (p<0.001) \) and 24 points more important \( (p<0.001) \). In all three cases this effect weakens as anti-intellectualism rises, though it does not entirely vanish for the most part.

</tr>
</tbody>
</table>

Perceived effectiveness of social distancing for decreasing the risk of infection and perceived social norms related to social distancing were strongly correlated with reported social distancing, suggesting that individuals engaged in social distancing if they thought it worked and if they thought their peers were doing it. If they learned that their social distancing behaviour would help others (e.g., family, older members of the community) and that there are serious health consequences for people like them, they would engage in more social distancing. Respondents in this group reported often getting news from national news networks and social media, followed by newspapers/news magazines. Respondents reported having the highest levels of trust in information from the CDC, public health experts, and the WHO. These groups were followed by university scientists and friends and family. The White House, state and local governments, and the news media were among the least trusted sources for information.

Appendix 6: Influences on effective public-health messaging

Most of the studies were qualitative work and reported on determinants of intent to adhering to guidelines by reporting what influences people’s responses to public health messaging. These are: preconceptions and understanding of the threat, perceived susceptibility and perceived risk severity (threat appraisal (Rogers, 1975)).

Preconceptions and understanding of the threat

Of the 68 studies included, 26 specified that public health messaging included information about the threat which can be effective in identifying symptoms and changing behaviours. Some of these, including the only randomised control trial, reported changes in hand washing (Yardley, Miller, Schlotz, & Little, 2011), changes in knowledge and higher compliance to quarantine (Kavanagh et al., 2011). However, this particular study found the messages were not effective in encouraging quarantine behaviour suggesting that increasing knowledge alone did not change behaviour (Kavanagh et al., 2011). More comprehensive reporting on what the threat is and looks like, including presentation of known and unknown factors has a positive impact on people’s knowledge, attitudes and beliefs. Self-reports, in the qualitative studies and in surveys, suggest changes in hygiene and unspecified protective behaviours following messages of how a virus (e.g. H1N1, SARS, Ebola) is transmitted, and the ability to identify symptoms, and how to prevent transmission (Chidgzey, Davis, Williams, & Reeve, 2015; Gray et al., 2012; Hickey, Gagnon, & Jitthai, 2014; Hoda, 2016; R. Li, Xie, Yang, & Frost, 2016; Rim, Ha, & Kiousis, 2014; Teasdale & Yardley, 2011; Yardley et al., 2011). In the systematic review, public health messaging campaigns using posters (e.g. “Catch it, Bin it, Kill it”) increased knowledge about transmission, and successfully increased self-reported prevention behaviours (hygiene when using tissues and sneezing). However, compliance to these behaviours was also predicted by worry (Lin, Savoia, Agboola, & Viswanath, 2014). The systematic review argued that individuals with higher education were better informed about H1N1. The review concluded that messages and communication are still delivered at a high literacy level (Lin, Savoia, et al., 2014). Whilst most of these papers highlighted that people will have different preconceptions and concerns to address in the public health messages, three papers also highlighted that people may have limited experiences of engaging in the preventative behaviour e.g. using face masks or using a thermometer (Hickey et al., 2014). Such cases highlighted a need for training/skill development as part of a public health campaign.

People that were able to identify symptoms of H1N1 were more likely to avoid crowds and washed hands more (Aburto et al., 2010). Framing and choice of language were found to be influential in behaviour and how individuals understand the threat (Teasdale & Yardley, 2011). Positively framed messages (emphasising the benefits of prevention behaviours) were considered ‘robust contingency measures’ (Basnyat & Lee, 2015). Gain-framed signs were significantly more effective in influencing the use of hand sanitizer as cue-to-action reminder signs at the point-of-use during the H1N1 pandemic (Updegraff, Emanuel, Gallagher, & Steinman, 2011). The worst-performing signs emphasised people’s susceptibility to contamination (Updegraff et al., 2011). Communication strategies were characterized in three case studies from the H1N1 pandemic from Italy, Hungary and England as “top-down” expert-led responses by public health communications specialists because there was no audience research. With no audience research, there was a perceived lack of planning and consideration to the tone, targeting or channelling of public health messages. Lack of consideration of these aspects led to low levels of public compliance and engagement with
behaviour (Crosier, McVey, & French, 2015). A non-narrative message format (i.e., factual) may be more effective than a narrative counterpart to communicate basic prevention information during public health emergencies. Compared with the narrative and/or fictional version, the more didactic and factual format was found to be more effective in changing knowledge and perceived response efficacy related to prevention of pandemic influenza however, behaviour or intent were not measured in the study (Bekalu, Bigman, McCloud, Lin, & Viswanath, 2018). When messages provided the public with clear consistent information whilst admitting that information is evolving, reported the risks, and focused on the practical actions that people can do to reduce their risk and emphasized the efficacy of those actions, people were more likely to clean objects, wash hands and use tissues when sneezing (Prati, Pietrantoni, & Zani, 2011). A pre-print manuscript found that for one to perceive and understand the extent of a threat, messages that are framed in relation to identity (e.g. “don’t be a spreader” vs “don’t spread”) were more likely to predict preventative behaviour following the Japanese Ministry of Health guidelines (Yonemitsu, 2020).

When individuals do not understand the message or the preventative behaviour being communicated, participants did not outright reject public health messages. Instead, people adjusted the key underlining message to what they thought made sense, and engaged in behaviour consistent with the adjusted message (Bonwitt et al., 2018). As there is general uncertainty around a pandemic flu it is hard for people to differentiate this from seasonal flu especially when symptoms are framed as “flu-like symptoms” (Teasdale & Yardley, 2011). In a qualitative study, people reported being more likely to follow guidelines when there were fewer perceived barriers to perform the recommended behaviours, when there are emphasised benefits and when contextual factors are considered such as feeling guilty and anxious about missing work and not wanting to let people down (Teasdale & Yardley, 2011). High levels of knowledge was associated with exposure to messages and was a mediator between different sources and complying with recommended protective behaviour. However, engaging with social media was associated with misconceptions of public health information (Winters et al., 2018).

**Threat appraisal: perceived susceptibility/vulnerability**

Increase in exposure to any type of information was associated with increased knowledge, and as level of outbreak increased (that increased the level of threat appraisal), protective behaviours increased, suggesting a strong dose-response (Johnson & Slovic, 2015; Winters et al., 2018). As perceptions of higher risk increase so did self-reported behaviours such as handwashing, wearing a facemask and using hand gels (Aburto et al., 2010). However, salience (i.e. prominence) in media coverage did not have a direct relationship with increasing perceived risk. One study found that there was no relationship between salience in media coverage of H1N1, or the severity of content and the public perception of risk (Rim et al., 2014).

Being worried about H1N1 was associated with media attention and number of H1N1 cases, and overall an important predictor of compliance with recommended preventative behaviours, such as using tissues, hand gel and washing hands (Lin, Savoia, et al., 2014). Worry led to effective compliance and increased adaptive behaviour in one included study (Gutteling, Terpstra, & Kerstholt, 2018). Evoking fear increased participants’ perceptions of the severity of the issue and their vulnerability to the risk but did not increase prevention behaviours or treatment efficacy (Chang, 2012). Moreover, panic could be counterproductive (Zikmund-Fisher, Scherer, Knaus, Das, & Fagerlin, 2017); providing a “worse-case” scenario (that there is a high risk and there is a pandemic) and increasing knowledge of the health threat simultaneously, has been found to induce panic in
those receiving the message (Jhummon-Mahadnac, Knott, & Marshall, 2012). Believability of messages was reduced by scepticism towards the media and governments; in these instances the threat was perceived as exaggerated and able to cause unnecessary panic which could influence low adoption of recommended action (Teasdale & Yardley, 2011). In a preprint manuscript, messages arousing an emotional response (such as fear) was more effective in boosting willingness to self-isolate alongside prosocial messages that are producing strong and positive emotional response (Heffner, 2020).

Perceiving a threat would mean that population warning systems (method where local, regional or national authorities contact the public en masse) can work but social pressure in addition to increasing perceived risk is also required (Gutteling et al., 2018). Worry about self or family members led to increased perceptions of disease severity and a stronger belief of being susceptible to the infection, leading to a greater compliance with recommended behaviours (Lin, Savoia, et al., 2014). Perceived susceptibility in the messaging (e.g. “this can happen to someone like me”) was more likely to lead to engagement in physical distancing than the geographical closeness of the disease (e.g. cases in the local area) thereby appraising the threat as high (Cole & Watkins, 2015). If risk is perceived to be low (e.g. H1N1 pandemic likened to influenza pandemics) recommendations such as “stay at home” were perceived as extreme and inappropriate (Teasdale & Yardley, 2011). This then has implications for increasing distrust in the messages and sources. Behaviours such as usage of a sanitizer dropped over time mapping the temporal trends in public interest in H1N1 (Updegraff et al., 2011).

Individuals were more likely to be concerned about the risk to themselves rather than the risk they would pose to others (M. D. Davis, Stephenson, Lohm, Waller, & Flowers, 2015). A recent systematic review concluded that beliefs about personal susceptibility to H1N1, and perceiving it as potentially severe (infection rate), is linked with high levels of worry about self or family members at risk (Lin, Savoia, et al., 2014). Efficient public health messaging (where individuals were more likely to comply with behaviour (e.g. avoiding crowds; (Aburto et al., 2010) tapped into worry about self or family members by framing messages with positive social responsibility (Basnyat & Lee, 2015). Concern for family led to reporting more information-seeking and appraising the threat as a higher risk to self and their family (Cole & Watkins, 2015). Prosocial framing and focus on activating social norms were found in the grey literature to be effective in increased engagement in physical distancing (Jordan, 2020; Wirz 2020). Tailoring public health messages with compassion may increase acceptance of the messages (Blagov, 2020). Such prosocial framing in the public health messaging personalised the risk and increasing the perceived susceptibility and vulnerability.

Increasing trust
An important finding that 60% of the included studies identified the need to increase the public’s trust in the messages during pandemics and epidemics (Aburto et al., 2010; Cole & Watkins, 2015; Gray et al., 2012; Hickey et al., 2014; Holmes, Henrich, Hancock, & Lestou, 2009; Jhummon-Mahadnac et al., 2012; Johnson & Slovic, 2015; Kavanagh et al., 2011; Liao, Cowling, Lam, Ng, & Fielding, 2010; Lohiniva, Sane, Sibenberg, Puumalainen, & Salminen, 2020; Lyu et al., 2013; Person et al., 2004; Prati et al., 2011; Qiu et al., 2018; Sumo et al., 2019). Participants cited trust as the main reason they complied, and observational studies found trust to be essential in complying with preventative behaviours (R. Li et al., 2016; Menon & Goh, 2005), both when communicating public health advice from public health agencies (Li et al., 2016) or from the government (Menon & Goh, 2005). Arguably, the need to increase trust highlights that acceptability of the message is reliant on
the right message given in the right way (framing cross-reference), by an appropriate messenger (cross-reference credible source) at the right time.

One of the systematic reviews, concluded that competing narratives should be addressed to support trust-building, and this can be achieved through involving the public with two-way communications in the design of the messages (Barrelet, Bourrier, Burton-Jeangros, & Schindler, 2013). Whilst the other systematic review, found that an honest reporting of what the threat looks like, through a presentation of known and unknown factors, seems to have a better impact on people’s knowledge, attitudes and beliefs, including trust in the way the government is handling the emergency (Lin, Savoia, et al., 2014).

In a repeated measures survey during H1N1 pandemic, trust levels in the government decreased over time, higher levels of government trust led to higher intention to adhere to the guidelines and change in trust was due to conflicting messages at the same time points and as they change over time (van der Weerd, Timmermans, Beaujean, Oudhoff, & van Steenbergen, 2011). Anxiety was mitigated by messages that were prompt and delivered at the right time for the point of the pandemic/epidemic, transparent, recommended preventative behaviours, and provided evolving outbreak trends (i.e. giving information as it happens) (R. Li et al., 2016). People are more likely to engage in behaviour inconsistent with the message if messages lack clarity or there is inconsistent messaging both over time and between sources. This eventually results in individuals distrusting the message. Therefore, one paper argues besides information and excessive exposure of such information there is also a need for behavioural modelling (to see the behaviour by others) (O. L. Davis, Fante, & Jacobi, 2013). Information in messages needs to be relevant and trustworthy to influence behaviour change and can include: catastrophic potential, probability of dying, and reasons for exposure. Providing explanations for perceived differences from other countries, not being too optimistic and not hide information can increase overall trust towards authorities (Lohiniva et al., 2020). Attempting to increase knowledge in the context of low levels of public trust in the source can make a message ineffective, and mistrust can increase if the perception is that the information is exaggerated (Jhummon-Mahadnac et al., 2012; Teasdale & Yardley, 2011). When an epidemic (e.g. Ebola) seemed contained, and contact tracing was successful, trust increased and, in response, so did the adherence to messages (e.g. reporting to health facility) (Sumo et al., 2019).

Multiple and credible sources

Individuals seek information from multiple sources to meet different information needs (Cole & Watkins, 2015). Whilst official sources of information (such as governmental sources, or public health bodies) are seen as legitimate, individuals do not always find them useful (Toppenberg-Pejcic et al., 2019; Tully, Dalrymple, & Young, 2019) thereby seek other sources. When official sources take a long time to provide information, individuals rely on informal sources such as rumours, word of mouth, social media (Cole & Watkins, 2015; van der Weerd et al., 2011); the value of information is at its highest when the outbreak is emerging. If mass media do not report the outbreak in time (before unofficial/informal sources start reporting the outbreak) it fails to become the leading indicator that people use for their information (J. Li, Xu, Cuomo, Purushothaman, & Mackey, 2020). Delay can impact the public’s trust in official sources (e.g. government) and has led to beliefs that the threat is exaggerated by government or news and media (J. Li et al., 2020; Teasdale & Yardley, 2011) especially when information is conflicting. Furthermore, a delay in addressing rumours
circulating among the public increases the chances of apathy and communication fatigue (Mitchell et al., 2014).

The grey literature reported that individuals seek information from sources that they consider trustworthy; these include public health experts, WHO and Centers for Disease Control and Prevention (CDC) and state and local governments; news media were the least trusted sources (Wirz 2020). Another preprint found that there was greater compliance and acceptance of messages when the messages came from government officials and credible sources (Abu-Akel, 2020). The effect on behaviour change (self-reported mask wearing and mask buying) from messaging was greater amongst individuals who trusted the Centers for Disease Control and Prevention (CDC), government agencies and scientists (M. H. Goldberg, Gustafson, A., Maibach, E.W., Ballew, M.T., Bergquist, P., Kotcher, J.E., Marlon, J.R., Rosenthal, S.A., Leiserowitz, A., 2020) and these messages were better received (Merkley, 2020). Explicit information, data safety and transparency were important (Bradshaw 2020) especially when describing protective behaviours (Dai, 2020). Whilst individuals generally preferred expert sources for the initial information-seeking, they eventually relied on other sources (and perceptions such as “anti-intellectualism” increased); eventually leading to discontinuing use of official sources for information during a pandemic (Merkley, 2020).

Community engagement and social networks

Social networks and close ties to the community are drivers of better knowledge and compliance with preventive measures. A systematic review suggests that non-traditional channels of communication (i.e. partnership with community leaders or organizations) should be used to reach out to the most vulnerable (can include those who have a disability e.g. hearing/vision/intellectual) and those who are least literate as well as non-Native speakers. Public health communication messages are still delivered at a literacy level that does not meet the needs of the less educated. To reduce communication inequalities, those who are less likely to identify risk associated with the threat and so less likely to adhere to the behaviours should be targeted. These include the young, least educated and hard to reach communities (Lin, Savoia, et al., 2014). The public pay more attention if the community is engaged in the intervention (Schiavo, May Leung, & Brown, 2014) as communication is a dynamic process and to address the concerns, values, interests and priorities the public need to be partners in communication (Barrelet et al., 2013).

The inclusion of various communities increases the chances of developing materials with which all individuals can identify (Crosier et al., 2015). This in turn increases the chances of perceiving the message is relevant to their self and important people in their lives thus heightening risk perception, and changing behaviours (Crouse Quinn, 2008; Gray et al., 2012; Person et al., 2004). Individuals want information that fits with their experiences (Freiman et al., 2011; Teasdale & Yardley, 2011). Adaptable and personalised information, that is context-driven, is more effective in changing determinants of behaviour (e.g. especially in vulnerable groups) (Daellenbach, Parkinson, & Krisjanous, 2018; Qiu et al., 2018). Core messages should be consistent to ensure trust but also considerations need to be made to ensure the involvement of communities to address their needs (e.g. including community leaders, translations, access to resources). Message delivery should be appropriate for the targeted population; for example, social media can open new avenues but should not to other types of delivery (Toppenberg-Pejcic et al., 2019). There is a use for social media, as it can be effective in communicating messages (Lwin, Lu, Sheldenkar, & Schulz, 2018), fostering trust and providing opportunities for dialogue (Tully et al., 2019). Social media can be especially
useful for reaching young people who trust social media channels (R. Li et al., 2016). Social-economic status (SES) is related to information access and understanding; those of lower SES were less likely to use a website, and more likely to find public health messages from TV and Radio to be confusing and contradictory than those of higher SES (Aburto et al., 2010).

The grey literature highlighted that developing prosocial messages and identity, increased willingness to self-isolate especially when producing a strong, positive emotional response (Heffner, 2020). Another preprint found that messages should not just target those who are at risk but those who do not perceive themselves at risk from COVID-19 (e.g. young people and hard to reach groups). Messages must also address barriers to physical distancing and outline benefits of carrying them out, emphasising altruism through messaging from credible sources using social media (Wirz 2020). Another preprint found that prosocial messages were the most effective type of framing, tapping into people’s sense of morality especially at the beginning of a pandemic. This changed over time and self-interest messaging were just as effective (Jordan, 2020).

**Messages for sub-populations**

Young (Student populations) and older adult populations

Three studies examined perceptions and experiences of H1N1 messages with student populations (Idoiaga, De Montes, & Valencia, 2016; Miczo, Danhour, Lester, & Bryant, 2013; Mitchell et al., 2014). An experimental study on framing found that younger students (mean age = 21.05) perceived themselves as less vulnerable than older students (over the age of 60) in falling ill with flu when reading a news report that described a flu epidemic (Idoiaga et al., 2016). The authors suggest this may be due to the ‘social invulnerability identity’ of younger people. This is consistent with social cognitive approaches to health risk perception, which suggests people may be “unrealistically optimistic” about a particular health threat (Weinstein, 1987).

Campus and mass media were reported, by students, as the most common places for getting information about the H1N1. Students tend to perceive information from the university as more credible than the media (Mitchell et al., 2014).

Focus groups exploring reactions to two different campaign ideas (for a potential avian influenza epidemic in Australia) found that there was some confusion amongst older adults whereby they presumed the ‘Wipe’ part of the WASH, WIPE, and WEAR message was referring to handkerchiefs, rather than disposable tissues. Older adults (and separately mothers) predominantly preferred messages which emphasised protecting others (e.g. that they should wear a mask if they were sick in order to protect others) (Jones, Waters, Holland, Bevins, & Iverson, 2010). On the other hand, regional and frequent travellers’ groups thought it was equally important to protect themselves from other people’s germs, and also protect others from their germs (Jones et al., 2010).

Vulnerable groups

The importance of both protecting themselves and others was evident in findings from focus groups conducted with vulnerable groups in New Zealand during the influenza H1N1 2009 pandemic (Gray et al., 2012). People wanted messages about specific actions that they could take to protect themselves and their families during the pandemic.
During the influenza H1N1 2009 pandemic, a cross-sectional survey was conducted with migrant workers (i.e., anyone who did not have Thai citizenship) to explore their perceptions of and ability to implement non-pharmaceutical interventions (NPIs; e.g., using face masks when sick) proposed by the WHO (Hickey et al., 2014). Certain groups of migrant workers were considered as a vulnerable group due to traditions in raising poultry and swine, poor personal hygiene and sanitation, low health literacy, limited access to healthcare, and high frequency of cross-border communication. Attitudes towards recommended NPIs were generally negative or ambivalent. Barriers included never having worn a face mask and not knowing the correct way to wear one. This highlights the need to educate vulnerable groups about performing NPIs during pandemics as migrants are at risk of propagating the spread of a pandemic virus. It is also important that public education campaigns can reach migrants living in remote and difficult to access areas, and to accommodate for the diverse cultural and linguistic needs.

The importance of ensuring that public health messages can reach different linguistic groups was also echoed by the Pacific Peoples’ participants in the focus groups conducted by Gray et al. (Gray et al., 2012). Older people in the group are unlikely to understand English so messages should be communicated in the original languages. However, as noted by Person et al., (Person et al., 2004) this can be very difficult when an in-house translation service does not exist, and the rapidly evolving scientific evidence will challenge the turnaround time for developing, translating, and disseminating information. To help address this, the team prioritised key SARS documents for translation and back-translations conducted by professional translation services ensured accuracy. The translated information should be disseminated through culturally appropriate channels such as community visits, town hall meetings, and health and education and communication channels to complement mass media messages. This is similar to reflections of Singapore’s experience in dealing with the SARS outbreak (Menon, 2006) where there was ongoing transparent dialogue with grassroots leaders and communities, and religious groups.

Social Economic Status (SES)

A cross-sectional survey with 1010 adult Italians during the influenza H1N1 2009 pandemic found that respondents who were women, and were facing economic hardship, were more likely to clean objects, wash their hands, and use tissues when sneezing (Prati et al., 2011).

A Mexican study, which explored the public’s ability and willingness to adopt community mitigation efforts during the influenza H1N1 2009 pandemic, found that respondents from lower SES groups were more likely to report costs of masks being a barrier to their use (Aburto et al., 2010). Respondents from lower SES tertials were also more likely to report that mitigation recommendations were contradictory or confusing. The authors highlight that it is important for future campaigns to tailor the messaging to people of lower SES who are more likely to have lower literacy levels and reduced ability to interpret messages. Messages should be coordinated, consistent, and simplified for these groups.

*Evaluation of messages at salient points in an epidemic/pandemic*

This presents the papers that had specific aims for the time of the study (either beginning, during, or post a pandemic/epidemic) and these are mapped to recommendations developed in this review. Evaluations collecting data at different time points over the course of a pandemic can tell us about any changes in patterns of public behaviour or perceptions as the situation evolves.

<tbody>
<tr>
<td>Address uncertainty</td>
<td>2. Deliver messages from a credible source in relatable terms to the target audience</td>
</tr>
<tr>
<td>Engaging communities</td>
<td>1. Minimise the ‘I’ and emphasise the ‘we’</td>
</tr>
<tr>
<td></td>
<td>4. Identify what influences each preventative behaviour and ensure policies, messaging and interventions target all relevant drivers</td>
</tr>
<tr>
<td></td>
<td>6. Avoid unintended negative consequences</td>
</tr>
<tr>
<td>Unified messaging</td>
<td>5. Clearly specify behaviours and their effectiveness</td>
</tr>
<tr>
<td></td>
<td>7. Create clear channels of access for health literacy</td>
</tr>
<tr>
<td></td>
<td>8. Use behavioural scientists and the psychological evidence base to support the COVID-19 response</td>
</tr>
<tr>
<td></td>
<td>9. Make a pledge to work together, through a multi-disciplinary approach. #CombatCovid19Together</td>
</tr>
<tr>
<td>Message framing</td>
<td>3. Create worry but not fear</td>
