S1 Analysis of Police-recorded Race Hate Crime in London

This analysis drew on publicly available police-recorded hate crime data from the London Metropolitan Police special crime dashboard (note: all raw data is available at Metropolitan Police, 2021). Given the limited categories of hate crime that are available through this service, sinophobic hate crime was operationalised as race hate crime, that is, criminal offences driven by bias towards the victim’s race, colour, nationality, or ethnic or national origin. ‘Race hate crime’ can be calculated by subtracting ‘anti-Semitic hate crime’, ‘Islamophobic hate crime’ and ‘faith hate crime’ from ‘racist and religious hate crime’. We analysed whether and how police-recorded race hate crime counts changed between July 2019 and July 2020.

Results showed that for race hate crime, a breakpoint model with one structural break in May 2020 fitted the observed data best (Table S1). After the national lockdown was lifted (and only then), race hate crime count increased significantly. There is thus no evidence of an increase in race hate crime following the COVID-19 outbreak.

Recruitment Text (some information is removed to allow for blind peer review)

I am a researcher from [text removed], and conduct a study on 'Hate during the COVID-19 crisis'. The aim of this study is to better understand people’s experiences with hateful comments or behaviour during the COVID-19 crisis in the UK. The study will take between 5 and 10 minutes to complete and you will be compensated £1.10 for your efforts.

You will be asked questions about your own experiences with hateful comments or behaviour in the last weeks, whether you have made such experiences and, if so, where these occurred. To be eligible for this study, you must currently live in the United Kingdom and NOT describe your ethnicity as White (e.g., White-British, White-Irish, White Other). Please follow the link, if you would like to learn more about the study and want to participate.

S5

**Analyses in which we weighted data in line with the distribution of different ethnic groups in the UK population**

To take into account that the distribution of participants from Chinese/East Asian descent and those of other ethnic minority groups in the sample did not reflect their distribution in the UK population, we weighted data in line with information available in the 2011 UK census.
According to the latter, in England/Wales, Scotland, and Northern Ireland, Chinese persons make up 5.65% of the non-White population; other non-White ethnicities represent 94.35%. Accordingly, sampling weights of .113 (for Chinese and East Asian participants) and 1.887 (for other participants) were computed.

We conducted the Chi-square test with the respective weights (Rao-Scott Method to take into account sampling variability and variability among the assigned weights) and identified significant differences between Chinese/East Asian persons and other participants ($F(1) = 24.24, p < .001$) with respect to the likelihood of having been victimised after the COVID-19 outbreak in the UK. Inspecting the weighted observed frequencies (Table S4), participants of Chinese/East Asian descent were OR = 2.89 times more likely to be victimised. Regarding victimisation after the COVID-19 outbreak, no between-group differences were detected ($F(1) = 2.15, p = .144$ (Table S5)).
