24 **Abstract**

25 Sustainable development requires improvement of both the quantity and quality of protected  
26 areas (PAs). This paper reviews the assessments of PAs' effectiveness and provides further  
27 guidance of using the assessment approaches, including: (1) evaluation based on a theory of  
28 change that describes how and why an intervention is supposed to work; (2) counterfactual  
29 evaluation using a random or constructed control group, or baseline of the treatment group as  
30 the counterfactual; (3) economic evaluation that assesses benefits and costs of interventions;  
31 (4) consultation; (5) case studies; (6) rapid assessments based on readily available evaluation  
32 sheets (e.g., scorecards); and (7) approaches focusing on a specific aspect of PAs (e.g.,  
33 ecological integrity, representativeness, and threats). These approaches have different  
34 characteristics and suitability to different assessment purposes and should be selected  
35 accordingly. For future research, we anticipate (1) an expanded PA effectiveness assessment  
36 guidebook integrating detailed instructions of the approaches and potential indicators, (2) more  
37 practical control-group-constructing techniques (3) more sophisticated and reliable techniques  
38 for valuing ecosystem services and biodiversity, and (4) further work to clarify the features of  
39 different evaluation sheets for rapid assessments. In terms of linkage with global initiatives,  
40 this review may help in the preparation of the National Reports (that indicate information on  
41 PAs' effectiveness) submitted to the Convention on Biological Diversity and evaluation of  
42 actions taken to fulfill PA-related goals of the United Nations Sustainable Development Goals,  
43 Convention to Combat Desertification 2018-2030 Strategic Framework, Paris Agreement, and  
44 especially Post-2020 Global Biodiversity Framework.

51 **1. Introduction**

52 A protected area (PA) denotes “a clearly defined geographical space, recognised, dedicated and  
53 managed, through legal or other effective means, to achieve the long-term conservation of  
54 nature with associated ecosystem services (ESs) and cultural values” (IUCN 2008). ESs are the  
55 benefits humans receive from functioning ecosystems (Millennium Ecosystem Assessment  
56 2005). PAs currently cover approximately 16.64% of global land and inland water ecosystems  
57 and 7.74% of coastal waters and the ocean (UNEP 2021). While the number and area of PAs,  
58 as well as recognition of PAs’ contributions to a sustainable future for all life on Earth, is  
59 growing (CBD 2020a), PAs must also improve their effectiveness, rather than being “paper  
60 parks” existing in name only (Di Minin and Toivonen 2015). Being effective means affecting,  
61 being needed for, or having relatively low costs for, the achievement of planned targets or  
62 desired outcomes (UNEP 2019). Hence, PAs’ effectiveness can be considered as the extent to  
63 which the policies/interventions of establishing and managing PAs contribute to expected  
64 environmental or socioeconomic changes, and the relative costs of achieving the goals.  
65 Effectiveness assessment addresses how and why PAs and their relevant interventions are  
66 contributing to desired outcomes or targets, reflects upon the likely outcomes from alternative  
67 policies, considers capacity of finance and staff, informs management adjustments, and  
68 considers improvement of the allocation of limited resources (GEF-6 2014; Geldmann et al.  
69 2018; Geldmann et al. 2019; Pomeroy et al. 2004).

70 However, assessments of PAs’ effectiveness remain challenging at the global level (Bacon et  
71 al. 2019; Gannon et al. 2019), and have been undertaken across only 18.29% of the area covered  
72 by PAs worldwide, well below the 60% target set by Parties to the CBD (UNEP-WCMC and  
73 IUCN 2021). This is partially because it can be difficult to identify suitable assessment  
74 approaches (Coad et al. 2015; Geldmann et al. 2021; UNEP-WCMC and IUCN 2021), while  
75 some toolkits and guidance on effectiveness assessment have been developed (Table 1). Hence,  
76 there is a continued need for further guidance of using the assessment approaches, including  
77 what the approaches are, how and when to use or improve the approaches, and what PA-related  
78 global targets the approaches may be used to assess. Compared to each of the guiding  
79 documents in Table 1, this review not only covers more comprehensive categories of  
80 approaches, but also, more importantly, further compares and explains how the approaches of  
81 different or the same categories differ from, share similarities with, or work better than, each  
82 other in specific real-world assessments. Moreover, this review suggests future research for  
83 improving the approaches’ applicability and outlines their linkage with several major global  
84 PA-related initiatives.

85 **Table 1:** A subset of guidance/reviews of approaches for assessing effectiveness

Documents	Main categories of assessment approaches

86 **Note:** The approach categories will be explained in the Results section. “X” indicates that a category is included.

87 Notably, effectiveness assessment approaches in different disciplines (e.g., medicine,

88 economics, environmental studies) may share the same rationales and principles (e.g., assessing

89 what changes are made) regardless of different assessment objects and indicators. We also  
90 acknowledge that interpretations of effectiveness may change in different regional contexts and  
91 assessments with different scopes of applicability. Moreover, when being scaled, PAs may  
92 change effectiveness in a nonlinear way.

## 93 **2. Methods**

94 We reviewed two groups of literature. The first was the CBD's literature, including two guiding  
95 documents of effectiveness assessment, the 5<sup>th</sup> National Reports of 193 Parties, the 6<sup>th</sup> National  
96 Reports of 189 Parties, and the latest versions of National Biodiversity Strategy and Action  
97 Plans of 196 Parties. These reports, especially the 6<sup>th</sup> National Reports, indicate the  
98 effectiveness of the Parties' PAs and associated assessment approaches. Therefore, the CBD's  
99 literature is a useful information source.

100 The second group was literature external to the CBD, including books and peer-reviewed  
101 papers in journals related to environmental studies, as well as official literature from  
102 governments, environmental NGOs, and inter-governmental international organisations. We  
103 reviewed the non-CBD guidance in Table 1 first, and then used Web of Science to search  
104 specific terms (Table 2) in English language in the topic, title, abstract, or keywords from 1<sup>st</sup>  
105 January 2000 to 28<sup>th</sup> February 2022 to include more literature. Search results were  
106 automatically ranked by relevance. We initially included the top 30 search results, and further  
107 checked their relevance by reading the titles, abstracts, or executive summaries to select the  
108 final literature for review (namely, some of the initial 30 results in each query were excluded  
109 after further relevance check). We also scanned references of the literature selected to identify  
110 over 30 additional articles.

111

112

113

114

115

116 **Table 2:** Search terms

Terms	Number of the total search results displayed	Number of the articles selected for final review
("protected area" OR "nature reserve" OR "national park" OR "conservation area") AND "effectiveness"	2,384	30
("protected area" OR "nature reserve" OR "national park" OR "conservation area") AND ("evaluation" OR "evaluating" OR "assessment" OR "assessing")	10,752	15
("policy effectiveness") AND ("evaluation" OR "evaluating" OR "assessment" OR "assessing") AND ("environment")	35	10
("impact evaluation" OR "evaluating impact") AND ("environment")	466	5

117 We collected effectiveness assessment approaches from the selected literature and added at  
118 least one empirical example to each specific approach. We analysed the approaches  
119 qualitatively, including what the approaches are, how and when to use or improve the  
120 approaches, and what PA-related global targets the approaches may be used to assess.  
121 Thereafter, we removed approaches with low applicability, such as the Management Analysis  
122 and Monitoring System controlled by the Brazilian government. Referring to existing guidance  
123 and our knowledge, we categorised the remaining approaches based on their features.  
124 Specifically, theory-based evaluation, economic evaluation, case studies, and consultation are  
125 common categories in the previous guidance (Table 1) and were adopted in this paper.  
126 Experimental, quasi-experimental, and non-experimental designs are also common types, but  
127 we categorised these three types of designs into counterfactual evaluation because they all need  
128 a counterfactual. Rapid assessments based on readily available evaluation sheets and  
129 approaches focusing on a specific aspect are not the categories used by the previous guidance  
130 (which only mentioned specific approaches in these two categories). Instead, these two  
131 categories were proposed by us, as they can summarise the features of the approaches in section  
132 3.6 and 3.7, respectively.

### 133 3. Results

134 The following categories of approaches are ordered based on the scope of their potential  
135 applicability (see more explanations of the applicability in section 4.1).

### 136 **3.1. Theory-based evaluation**

137 Theory-based evaluation uses a theory of change throughout the causal chain of a policy (Jacob  
138 et al. 2019), and considers why and how an intervention did or did not work (GEF 2019). A  
139 theory of change is “a description of how an intervention is supposed to deliver the desired  
140 results. It describes the causal logic of how and why a particular program, program modality,  
141 or design innovation will reach its intended outcomes” (Gertler et al. 2016, p. 32). All  
142 effectiveness assessments should be underpinned by theories of change and hence are theory-  
143 based evaluation (Gertler et al. 2016). Theories of change have also been used as frameworks  
144 to guide planning and implementation of conservation (Balfour et al. 2019; Rice et al. 2020).

145 General steps of theory-based evaluation include (CBD 2015, 2017): (1) developing a theory  
146 of change based on certain assumptions and rationales, which can be derived from literature or  
147 information gathered through field work, interviews, and observation of policymaking; (2)  
148 identifying which outputs, outcomes and causal links data should be collected, and (3)  
149 analysing and drawing conclusion about the logic between the interventions and expected  
150 outcomes.

151 While developing a theory of change can be time-consuming or lack sufficient data, a less-  
152 detailed theory of change with less testing may be used in low-risk or low-complexity programs  
153 where the tolerance for uncertainty in attribution is higher. If multiple theories of change  
154 emerge, evaluators may need to analyse where the theories differ, explore the reasons for, and  
155 implications of, the differences, and test which theory best reflects the reality (Treasury Board  
156 of Canada Secretariat 2021). Notably, Salafsky et al. (2021) introduced a series featuring  
157 conservation-related theories of change, such as how and why community-led business affected  
158 conservation (Boshoven et al. 2022).

159 Theory-based evaluation may involve (1) realistic synthesis/review that interrogates the  
160 existing evidence and produces a causal narrative of the intervention, for example, which  
161 intermediate steps are required to produce the outcomes, and how different contextual features  
162 may affect the intervention (Buseti 2019); (2) contribution analysis that verifies a theory of  
163 change (e.g., if a theory is plausible; if expected results have occurred) and considers other  
164 influencing factors to assess interventions’ contributions to observed results; (3) outcome

165 harvesting that collects evidence of what has been achieved, and works backward to determine  
166 whether and how interventions have contributed to observed change (Wilson-Grau and Britt  
167 2012); and (4) a results chain that uses a series of expected intermediate results to depict the  
168 assumed causal linkage between interventions and desired impacts (Margoluis et al. 2013).

## 169 **3.2. Counterfactual evaluation**

170 Counterfactual evaluation disentangles the effects attributable to an intervention on an outcome  
171 variable (Ahmadia et al. 2015; Varian 2016), measures what would have happened in the  
172 absence of the intervention, and identifies what works and what doesn't (Karousakis 2018).  
173 This approach compares the outcomes (1) before and after the intervention, and (2) with and  
174 without the intervention. 'Before–after' analyses assume that the outcome level (or trend) of  
175 the treatment group before the intervention would remain constant. 'With–without' analyses  
176 assume that the control and treatment group have similar expected outcomes in the absence of  
177 the intervention, and there are no spill-over effects from the treatment group to the control  
178 group (Karousakis 2018). However, in practice, spill-over effects have been observed in some  
179 PA assessments (Black and Anthony 2022; Fuller et al. 2019).

180 Counterfactual evaluation has the following subcategories.

### 181 **3.2.1. Experimental designs**

182 Experimental designs (may also be termed as “randomisation” or “random controlled trial”)  
183 use a randomly-assigned control group as the counterfactual, and only give intervention to the  
184 treatment group (CBD 2017). However, the objects of policy interventions are often complex  
185 systems, hence it can be infeasible to identify a random control group. Also, it may be unethical  
186 to deliberately withhold the benefits of an intervention (Jacob et al. 2019).

187 An experimental design (Martin et al. 2014) compared the conservation outcomes in the  
188 Nyungwe National Park in Rwanda with that in several randomly selected areas adjacent to the  
189 park, finding that payment for ESs improved the motives for conservation.

190

191

### 192 **3.2.2. Quasi-experimental designs**

193 Quasi-experimental designs are widely used in situations where it is infeasible to conduct  
194 random experimental designs (e.g., due to endogenous problem) but still possible to identify a  
195 treatment group and construct a control group through several techniques below (CBD 2017;  
196 Wooldridge 2015).

197 (1) Traditional ordinary least squares regression

198 The traditional ordinary least squares (OLS) regression estimates the relationship between two  
199 interval/ratio variables, if the observations, when displayed in a scatterplot, can be  
200 approximated by a straight line. A vector of additional relevant variables is controlled to  
201 capture shocks from other factors and to address potential omitted variable concern. Using OLS  
202 regression, Abman (2018) analysed the macro-level relationship between rule of law and  
203 variation in avoided deforestation from PAs in 71 countries between 2000 and 2012, indicating  
204 that PAs' effectiveness was higher in countries with higher levels of corruption control,  
205 protection of property rights, and democracy.

206 (2) Instrumental variable method

207 A major concern of measuring continuous policy variable using traditional OLS regression is  
208 the potential endogeneity challenge. For example, there may be a third factor that affects both  
209 the independent and dependent variables simultaneously. Omitted control variables and reverse  
210 causality may also lead to endogeneity issues. To improve credibility of effectiveness  
211 assessment when the exposure to an intervention is to a certain degree determined by an  
212 external force, assessments can use the instrumental variable (IV) method that instruments the  
213 potential endogenous independent variables (Karousakis 2018). A good IV should be a  
214 significant contributor to the instrumented variables and affect the dependent variables only  
215 through the instrumented variables rather than other mechanisms. Other channels should be  
216 controlled in the regression. The IV method includes two-stage least square, three-stage least  
217 square, maximum likelihood, and generalised method of moments. With the IV method, Butsic  
218 et al. (2015) assessed how the conflicts between PAs and endogenous variables (mining and  
219 warfare) affected PAs' effectiveness of reducing deforestation in the Democratic Republic of  
220 Congo.

221

222 (3) Difference-in-difference

223 However, environmental policies may be measured as dummy variables (e.g., happen or not),  
224 rather than continuous variables. Therefore, difference-in-difference (DID) compares the  
225 changes in outcomes by computing a double difference: one over time (before-after) and one  
226 across subjects (between treated group and control group) (Donald and Lang 2007). Simply  
227 observing the before and after change in the treatment group is not sufficient as there may be  
228 other factors influencing the outcome over time. Simply comparing the treatment and control  
229 group is also insufficient. DID assumes that unobserved differences in the treatment group are  
230 linear and time-invariant, corresponding to the observed difference in the outcomes of the  
231 control group before and after intervention (Karousakis 2018). DID sets a dummy variable of  
232 with or without an intervention in regression and can reduce endogenous problems (policies  
233 are typically exogenous). Generally, the validity check of the underlying assumption of equal  
234 trends will be assessed via a “placebo” test. The control group will receive a placebo treatment,  
235 in which an additional DID estimation using a “fake” treatment group is performed. A fake  
236 group means a group that you know was not affected by the intervention.

237 Gertler et al. (2016) explained: provided that the outcomes of the control group before and after  
238 policy intervention are 0.78 and 0.81 respectively, 0.03 (0.81–0.78) would be the observed  
239 change in the control group, namely the unobserved change in the treatment group; provided  
240 that the outcomes of the treatment group before and after policy implementation are 0.74 and  
241 0.60 respectively, the observed change in the treatment group would be 0.14 (0.74–0.60); in  
242 the treatment group, the unobserved difference should be removed from the observed  
243 differences to reflect the policy impact. Hence, the policy impact should be 0.11 (0.14–0.03).

244 Using DID, Shi et al. (2020) revealed the effects of constructing PAs worldwide from 1994 to  
245 2015 on global carbon sequestration capacity via separating the time effect and policy effect.

#### 246 (4) Regression discontinuity design

247 A regression discontinuity design (RDD) is used for programs that have a continuous eligibility  
248 index with a clearly defined eligibility threshold (cut-off score) to determine what is eligible  
249 and what is not. The index has to meet 4 criteria: (1) ranking people or units in a continuous  
250 way; (2) having a clearly defined cut-off score above or below which the assessment target is  
251 classified as eligible for the program; (3) the cut-off must be unique to the program of interest;  
252 and (4) the score of a particular individual or unit cannot be manipulated by enumerators,  
253 potential beneficiaries, program administrators, or politicians (Gertler et al. 2016). When

254 strictly cut-off-based assignment to conditions is given, a RDD can alleviate the endogenous  
255 problem of parameter estimation (Kelava et al. 2010). However, “it has lower statistical power,  
256 it is more dependent on statistical modelling assumptions, and its treatment effect estimates are  
257 limited to the narrow subpopulation of cases immediately around the cut-off” (Wing and Cook  
258 2013, p. 853).

259 Bonilla-Mejía and Higuera-Mendieta (2019) undertook a spatial RDD to assess how local  
260 institutions (natural resource consumption, proximity to markets, improved enforcement of  
261 conservation law) shape PAs’ effectiveness in deforestation reduction in Colombia.

## 262 (5) Matching

263 Matching means “the control group is constructed to make it resemble as much as possible the  
264 treatment group, based on observed characteristics. If resemblance is satisfactory, the outcome  
265 observed for the matched group approximates the counterfactual, and the effect of the  
266 intervention is estimated as the difference between the average outcomes of the two groups”  
267 (Karousakis 2018, p. 30). Matching method assumes: (1) the treatment received by one does  
268 not affect outcomes for another; (2) there are no unobserved characteristics; and (3) for each  
269 participant there exists at least one “twin” nonparticipant having the same observed  
270 characteristics (OECD 2012). Matching can avoid selection bias caused by observables but  
271 cannot address bias caused by un-observables (Karousakis 2018).

272 Matching can eliminate selective errors via seeking a control group which is the closest to the  
273 treated group to identify causal inference. It mainly includes covariant matching, coarsened  
274 exact matching, mahalanobis metric matching, propensity score matching, and entropy  
275 balancing matching (Stuart 2010). However, matching requires a large dataset, because a small  
276 number of observations may reduce the accuracy of causal inference.

277 Using matching, Ahmadi et al. (2015) assessed effectiveness of the marine PAs in the Birds'  
278 Head Seascape, Indonesia. They constructed a control group through selecting outside reef  
279 areas similar to reefs in the PAs (non-matched ones were dropped from the sample), using  
280 statistical models to reduce observation bias, and conducting indicator-based monitoring on  
281 ecosystem conditions of reefs both outside and inside the PAs.

282

283 **3.2.3. Non-experimental designs**

284 Non-experimental designs assume that any observed changes are the result of the intervention  
285 taken and that the impacts and progress of the intervention are observable at the time the  
286 evaluation is undertaken, and hence it does not use a control group (CBD 2017). Instead, it  
287 uses a benchmark or baseline of the treatment group as the counterfactual and compares current  
288 performance/condition with one or more benchmarks/baselines (Coglianese 2012).

289 There are (1) before-and-after comparisons (or pre-test/post-test): conditions of the treatment  
290 group before and after an intervention are compared (e.g., the CBD 6<sup>th</sup> National Report of  
291 Albania indicated its PA strategy was effective because its PA coverage has improved since  
292 2015); (2) actual-versus-planned comparison: the anticipated outcomes of an intervention are  
293 compared with the outcomes actually achieved (e.g., the CBD 6<sup>th</sup> National Report of  
294 Afghanistan indicated its PAs were partially effective for wildlife conservation, as the  
295 population of several protected species increased but did not fully met the targeted population);  
296 and (3) formative/developmental evaluation: this compares the differences between how a  
297 policy is designed and implemented without considering the policy outcomes (e.g., the CBD  
298 6<sup>th</sup> ational Report of Greece indicated its PA network expansion initiative was partially  
299 effective, as demarcation of PAs was completed but the development of specific management  
300 plan was incomplete) (CBD 2017, 2022b).

301 There are more specific techniques developed to conduct actual-versus-planned comparison in  
302 PAs. Based on several indicators (e.g., staff skills, quality of infrastructure and recreation), PA  
303 scenery matrix compares an optimal PA scenario scored at 4 with the actual PA situation scored  
304 from 0 to 4 (Leverington et al. 2008). Pauquet (2005) used the PA consolidation index to  
305 assigns values to different management aspects (e.g., finance, administration) of desired and  
306 actual PA situations in Bolivia.

307 **3.3. Economic evaluation**

308 Economic evaluation considers the outcomes and costs of an intervention, how far objectives  
309 or outcomes have been achieved at what cost, and which intervention works the best if there  
310 are multiple alternative interventions (Karousakis 2018). Generally, it is more difficult to  
311 determine benefits than costs (CBD 2017).

312

313 **3.3.1. Cost-benefit analysis**

314 Cost-benefit analysis is typically quantitative and considers if the intervention's benefits  
315 outweigh the costs in monetary units (Rowe et al. 2012). When counting the costs, it should  
316 consider direct expenditure, transaction costs, overall social cost, and opportunity costs (CBD  
317 2017; UNEP 2019).

318 Basic valuation techniques in monetary units consist of (1) revealed-preference approaches that  
319 infer preferences from observed choices in reality, such as market price of ecosystem goods,  
320 and travel costs (including direct travel expenses and opportunity costs of time) spent for  
321 interaction (e.g., recreation) with a natural site (Chen 2020; United Nations et al. 2021); (2)  
322 cost-based approaches, including replacement cost of using artificial alternatives to replace ESs,  
323 damage cost avoided by the existence of ecosystems, restoration cost needed to restore  
324 degraded ecosystems, and economic loss resulted from ES degradation (Chen et al. 2022;  
325 Farber et al. 2006); (3) stated-preference approach that infers preferences by asking separate  
326 individuals hypothetical questions, including contingent valuation that directly asks people's  
327 preferences (e.g. how much are you willing to pay for conserving this forest?) and choice  
328 experiment that tests how people trade off different choices with alternative supply levels or  
329 characteristics of ESs and biodiversity (Bateman et al. 2002); (4) deliberative valuation that  
330 asks people to state preferences through deliberation, which aims to improve credibility and  
331 fairness of value elicitation by enabling people to explain reasoning of preference expression,  
332 understand preferences of others, and improve knowledge of ESs (Kenter 2016); (5) benefit  
333 transfer that estimates the value of ESs at a new site by transferring and adjusting previous  
334 value estimates of the same ESs from one or multiple sites (Kubiszewski et al. 2013); and (6)  
335 economic modelling (e.g., price of raw materials elicited from computable equilibrium models)  
336 that encompass information on environmental and economic variables (United Nations et al.  
337 2021).

338 Using market price, replacement costs, avoided damage costs, and travel costs, Chen (2021)  
339 valued a subset of ESs of China's terrestrial PAs to be \$2.64 trillion/yr, corresponding to over  
340 14 times the costs required to maintain the PAs.

341 **3.3.2. Cost-effectiveness analysis**

342 Cost-effectiveness denotes the relative costs of achieving per unit of outcomes, and can be  
343 calculated by dividing the cost by the benefits (UNEP 2019). Cost-effectiveness analysis seeks

344 the most economical intervention (with the minimum relative resource use) through comparing  
345 the costs of multiple alternative interventions in reaching the same objective or comparing the  
346 outcomes of multiple alternative interventions with the same costs (CBD 2017; Wätzold and  
347 Schwerdtner 2005).

348 Cost-effectiveness analysis can be either quantitative or qualitative, and can express costs and  
349 benefits in both monetary and physical units, such as tons of waste eliminated. Thus, cost-  
350 effectiveness analysis is sometimes used in place of cost-benefit analysis when assessors are  
351 unable or uncertain to monetise benefits or costs (UNEP 2019).

352 Wei et al. (2018) assessed the cost-effectiveness of several alternative scenarios regarding  
353 managing the Giant Panda Nature Reserves in China: (1) maintaining management of the  
354 reserves, (2) improving management of the reserves by 15% through allocating more sufficient  
355 staff, (3) expanding the reserves by 15% and improving the management by 15%, and (4)  
356 management degradation by 20% due to reduced funding, staff number, and forest area. The  
357 cost-effectiveness of these scenarios was 10.2, 10.7, 11, and 8.4, respectively, implying  
358 Scenario 3 was the most cost-effective.

### 359 **3.3.3. Input-output analysis**

360 Input-output analysis identifies the drivers of economics activities, calculates input into and  
361 environmental impacts (output) from economic activities, and compiles the inputs and outputs  
362 into a matrix or table for analysis (UNEP 2019). Input-output analysis may also assess the  
363 interaction between financial investment (input) in PAs and financial profits (output) generated  
364 from economic activities in PAs. For example, Beraldo-Souza et al. (2019) found that “each  
365 dollar Brazil invested in the PA system produced \$7 in economic benefits” (p. 735).

### 366 **3.4. Stakeholder and/or expert consultation**

367 Consulting stakeholders and experts via workshops, questionnaires, or interviews can bring  
368 additional views, knowledge, experiences, or skills to conduct, improve, or adjust effectiveness  
369 assessment. Consultation is relatively subjective but widely conducted, including the CBD 6<sup>th</sup>  
370 National Reports of Afghanistan, Bangladesh, Costa Rica, Cuba, Dominica, Eritrea, Fiji,  
371 Germany, Ghana, Guinea, Guyana, Kyrgyzstan, Laos, Lesotho, Monaco, Niue, Solomon  
372 Islands, South Sudan, Timor-Leste, Tonga, Vanuatu, Vietnam, Yemen, and Zimbabwe

373 (CBD 2022b). Roux et al. (2021) engaged stakeholders into effectiveness assessment of  
374 the Garden Route National Park in South Africa.

375 A well-known expert consultation method is the delphi method (Okoli and Pawlowski 2004;  
376 Schmidt et al. 2001): Experts are asked questions for several rounds, and anonymous responses  
377 are aggregated and shared with the group after each round. The experts are allowed to adjust  
378 their answers in subsequent rounds, based their interpretations of the group response provided  
379 to them. After multiple rounds of asking and responding questions, the experts may understand  
380 what the group thinks as a whole and seek consensus. Mehnen et al. (2013) conducted delphi  
381 method to assess the advantages, disadvantages, and governance performance of PAs of  
382 different IUCN categories (IUCN 2008).

### 383 **3.5. Case study evaluation**

384 Case study evaluation addresses “how and why a given measure has worked or not by looking  
385 at a specific real-world situation” (CBD 2017, p. 4). It usually includes four steps (McCombes  
386 2020): (1) selecting a case that provides new or unexpected insights into the subject, challenges  
387 existing assumptions and theories, proposes practical actions to address an issue, or suggests  
388 future research; (2) building a theoretical framework, including exemplifying how a theory  
389 explains the case under investigation, expanding on a theory by integrating new ideas, or  
390 challenging a theory by exploring an outlier case that does not fit with established assumptions;  
391 (3) data collection; and (4) describing and analysing the case based on research type, purpose,  
392 and data availability. According to Morra and Friedlander (1999), there are:

393 (1) explanatory case studies that (a) explain the relationships among program components; (b)  
394 investigate operations, often at several sites, and often with reference to a set of norms or  
395 standards about implementation processes; and (c) examine causality between the program  
396 and observed outcomes.

397 (2) Descriptive case studies that (a) add realism and in-depth examples to other information  
398 about an intervention; (b) generate hypotheses for later investigation; and (c) examine a  
399 single instance of unique interest or serve as a critical test of an assertion about the  
400 intervention.

401 (3) Cumulative case studies that combine cases with different methodologies and findings to  
402 answer a question.

403 As an example, the Great Barrier Reef Marine PA in Australia is a popular case for assessing  
 404 effectiveness of controlling marine pollution caused by agriculture production (Eberhard et al.  
 405 2021; Rolfe et al. 2018).

406 **3.6. Rapid assessments**

407 Rapid assessments are typically built upon the IUCN’s World Commission on Protected Areas  
 408 (WCPA) Framework (Table 3) and use readily available evaluation sheets, including  
 409 scorecards, worksheets, questionnaires, and process diagrams (Table 4) (The Nature  
 410 Conservancy 2018).

411 **Table 3:** Summary of the WCPA Framework

Evaluation elements	Explanations	Criteria
Context	Where are we now? Assessment of importance, threats, and policy environment	Significance, threats, vulnerability, context, and partners
Planning	Where do we want to be? Assessment of design and planning	Legislation, policy design, reserve design, and management planning
Inputs	What do we need? Assessment of resources needed	Resourcing of agency and site
Processes	How do we go about it? Assessment of the ways in which management is conducted	Suitability of management process
Outputs	What are the results? Assessment of delivery of products and services	Results of management actions, services, products
Outcomes	What did we achieve? Assessment of the outcomes and the extent to which objectives are achieved	Effects of management in relation to objectives

412 **Source:** (Stolton et al. 2007)

413 **Table 4:** Tools for rapid assessments

Tools	Sources of instructions and sample evaluation sheets	CBD assessment reports (if applicable) and other assessments integrating the approaches
Marine Protected Area Management Effectiveness Assessment Tool	(National CTI Committee 2011)	CBD 6 <sup>th</sup> National Report of Malaysia (CBD 2022b)
Micronesia Protected Areas Management Effectiveness tool	(Micronesia Islands Nature Alliance 2017)	CBD 5 <sup>th</sup> National Report of Federated States of Micronesia (CBD 2022b)
Management Effectiveness Tracking Tool	(Stolton et al. 2007)	CBD 6 <sup>th</sup> National Reports of the Democratic Republic of the Democratic Republic of Congo, Dominica, Equatoria Guinea, Jamaica, Laos, Papua New Guinea, Sierra Leone, and Thailand (CBD 2022b)
WWF Rapid Assessment and Prioritization of Protected Area Management Methodology	(Ervin 2003)	CBD 6 <sup>th</sup> National Reports of the Democratic Republic of Congo and Papua New Guinea (CBD 2022b)
Enhancing our Heritage Toolkit	(World Heritage Centre 2008)	The Keoladeo National Park, India, and Sangay National Park, Ecuador, and the Bwindi Impenetrable National Park, Uganda (World Heritage Centre 2008)
World Heritage Outlook Assessment	(IUCN 2012, 2019)	CBD 6 <sup>th</sup> National Report of the Democratic Republic of Congo (CBD 2022b)
Integrated Management Effectiveness Tool	(BIOPAMA 2021; IUCN 2020; Paolini et al. 2015)	CBD 6 <sup>th</sup> National Report of the Democratic Republic of Congo (CBD 2022b)
Financial Sustainability Scorecard	(Bovarnick 2010)	CBD 3 <sup>rd</sup> National Biodiversity Strategies and Action Plan of Niger (CBD 2022a)

WWF-World Bank Marine Protected Area Score Card	(Gomei et al. 2019; Leverington et al. 2008; Staub and Hatzios 2004)	The habitat representativity, replication and connectivity of marine PAs in Mediterranean countries (Gomei et al. 2019)
West Indian Ocean Workbook	(Wells and Mangubhai 2004)	Kenya (Kisite/Mpunguti, Mombasa, Malindi, and Watamu Marine National Parks and Reserves, and Kiunga Marine National Reserve), Tanzania (Mafia Island and Mnazi Bay-Ruvuma Estuary Marine Parks) and Seychelles (Cousin Island Special Reserve) (Wells and Mangubhai 2004).
Site Consolidation Scorecard	(The Nature Conservancy 2003a).	The Parks in Peril program throughout Latin America and the Caribbean (The Nature Conservancy 2003a)
Park Watch Questionnaire	(Park Watch 2006)	Management of biodiversity and ESs in Peru's PAs (Park Watch 2006)
Mesoamerica Marine Protected Areas Scorecard	(Corrales 2004)	Marine PAs in Mesoamerica (Corrales 2004)
How is your marine protected area doing?	(Pomeroy et al. 2004)	24 marine PAs across the world (Fox et al. 2014)
Important Bird Areas	(BirdLife International 2006)	30 important bird areas in Uganda (Tushabe et al. 2006)
Headline indicators	(Leverington et al. 2010)	37 PAs in Krasnoyarsk Kray, Russia (Anthony and Shestakova 2015)

415 **3.7. Additional approaches**

416 **3.7.1. Spatial monitoring and reporting tool**

417 Based on the SMART<sup>1</sup> software, a spatial monitoring and reporting tool helps streamline data  
418 collection, analysis, reporting, and transferring information obtained from the field to  
419 decision-makers. It is used to assess effectiveness of enforcement of conservation/wildlife  
420 law, patrol, and site-based conservation activities. Its instructions can be found in SMART  
421 (2021). The CBD 6<sup>th</sup> National Reports of Cambodia, Laos, and Pakistan have undertaken this  
422 tool to assess their PAs (CBD 2022b).

423 **3.7.2. Gap analysis**

424 Gap analysis matches maps of vegetation and species distributions with the maps of  
425 conservation areas to show how well vegetation alliances and species are represented in the  
426 existing conservation network. Those that are neither adapted to human-dominated  
427 environment nor adequately represented in PAs are identified as ‘gaps’ and become the focus  
428 for further conservation work (Jennings 2000; Weeks et al. 2010). Weeks et al. (2010) assessed  
429 how well marine PAs in the Philippines represented marine bioregions, conservation priority  
430 areas, and marine corridors. Moreover, gap analysis can be integrated in systematic  
431 conservation planning, the process for selecting between, locating, and implementing informed  
432 conservation actions (McIntosh et al. 2017). This includes reviewing existing conservation  
433 areas (e.g., to which extent targeted ecological representation has been achieved) and selecting  
434 additional conservation areas (Margules and Pressey 2000).

435 **3.7.3. Ecological Integrity Framework**

436 This framework sets conservation goals and measures success, viability, or ecological integrity  
437 of focal biodiversity at multiple scales, and consists of the four components (The Nature  
438 Conservancy 2003b): (1) identification of key ecological attributes that determine the  
439 composition, structure, and function of focal biodiversity, including characteristics of  
440 biological composition and its spatial structure, biotic interactions, environmental regimes and  
441 constraints that shape habitat conditions, and ecological connectivity that affects the ability of  
442 species to move and maintain diversity at genetic, species, and ecosystem levels; (2)  
443 identification of indicators to describe key attribute status; 3) determination of acceptable

---

<sup>1</sup> <https://smartconservationtools.org>

444 ranges of variation for key attributes based on reference conditions, and establishment of  
445 minimum integrity threshold criteria for conservation; 4) rating of key attribute status and  
446 assessment and monitoring of overall integrity status based on status of all key attributes. The  
447 US National Park Service has used this framework to assess effectiveness of managing  
448 ecological integrity in PAs (Unnasch et al. 2009).

#### 449 **3.7.4. Threat reduction methodology**

450 This methodology uses on-site discussion groups comprising representatives of community,  
451 PA staff, and other experts to list and rank (e.g., from 1 to 5) threats to the PAs' habitat integrity,  
452 quality, and ecosystem functioning, and consider how fast and which area the threats could  
453 harm the PAs. The groups then evaluate the extent (from 0% -100%) to which the threats are  
454 being addressed (Leverington et al. 2008). This methodology is simple and low-cost but is  
455 difficult to assess reduction of internal threats (e.g., overhunting or over-farming in PAs),  
456 especially when the threat-evaluating information comes from the actors responsible for the  
457 threats (Margoluis and Salafsky 2001). Standardisation of threat types can promote comparison  
458 of temporal and spatial variation across sites and enhance cross-project learning (e.g.,  
459 transferring mitigation strategies) (Anthony 2008). The IUCN Standard Lexicon of Threats  
460 (Salafsky et al. 2008) has been integrated in some cases, such as the Horsh Ehdén Nature  
461 Reserve, Lebanon (Matar and Anthony 2010).

## 462 **4. Discussion**

### 463 **4.1. General suitability of different approaches**

464 In terms of potential applicability, (1) theory-based evaluation is integrated into all types of  
465 effectiveness assessments. (2) Counterfactual evaluation is often used to assess changes caused  
466 by an intervention. (3) Economic evaluation complements counterfactual evaluation with  
467 assessment of economic preference for an intervention. (4) Unlike the previous three categories  
468 used for primary assessments, consultation uses second-hand knowledge. (5) Case studies are  
469 used when it is not feasible, necessary, or desirable to assess effectiveness nationwide or  
470 worldwide but in specific cases. (6) Rapid assessments based on readily available evaluation  
471 sheets are specific to PAs, while the previous five categories are also applicable to many other  
472 fields. (7) Applicability of approaches focusing on a specific aspect of PAs is narrower than  
473 the previous six categories that potentially assess multiple aspects of PAs. Table 5 summarises  
474 the conditions for use, strengths, and weaknesses of these seven categories of approaches.

475 **Table 5:** Suitability of different approaches

Approaches	Conditions for use	Strengths	Weaknesses
Theory-based evaluation	All effectiveness assessments are theory-based evaluation.	Developing, integrating, explaining or verifying a theory of change is essential to understanding why an intervention works or not (Gertler et al. 2016).	Developing theories of change can be challenging
Counterfactual evaluation	Assessments intend to understand impacts from interventions. Experimental and quasi-experimental designs are applicable when random or constructed control groups are available, respectively. Non-experimental designs do not need control groups but use a baseline of the treatment group as the counterfactual.	Counterfactual evaluation addresses whether an intervention works or not. Notably, quasi-experimental designs tend to be more suitable than experimental designs (when it is impossible to use random control groups) and non-experimental designs (that lack rigorousness and credibility).	Counterfactual evaluation does not consider whether an intervention is economical. It may be infeasible to use random control groups for experimental designs in complex systems. Assessors may lack skills or knowledge to construct control groups for quasi-experimental designs. Non-experimental designs require less expertise and techniques and tend to be easier than experimental and quasi-experimental designs. However, they simplify the reality and are less rigorous to analyse causal relationships (Coglianese 2012). Hence, they are normally used in grey literature (e.g., the CBD National Reports), rather than peer-reviewed academic literature.
Economic evaluation	Assessments intend to measure if an intervention is economical.	Economic evaluation considers efficiency (cost-benefit analysis), economic preferences for alternative interventions (cost-effectiveness analysis), and environmental impacts, financial outputs, and financial inputs of an	Critiques against ES valuation include potentially commercialising nature and being anthropocentric (Schröter et al. 2014). Valuation techniques also have limitations: (1) market price may be distorted, (2) deliberative valuation can be expensive and time-consuming; (3) preferences stated by separate individuals may ignore social welfare; (4) travel costs method

		intervention (input-output analysis).	assumes the single purpose of visiting a natural site to be interaction with nature; and (5) benefit transfer simplifies the differences of ecological and socioeconomic contexts between sites (Chen 2021; Costanza 2020).
Rapid assessment	There are readily available evaluation sheets	Many types of evaluation sheets have been developed to provide assessors with multiple options for assessments that can be rapid and convenient.	Existing evaluation sheets are prone to interviewee bias, variation in participants' opinions, disparity between the selection and weights of indicators used and stated PA outcomes, mutual exclusivity and inclusivity of responses, and differing operating conditions/scales of assessments (Anthony 2014). They also share similarities but lack features demonstrating how each of them differs from the others, in terms of data requirement, assessment objectives, strengths, and limitations. This makes it challenging for assessors to select the best suited option from multiple available evaluation sheets.
Consultation	Assessments need knowledge and skills of consultants.	Consultation may bring additional views to assessments.	Consultation is dependent on subjective opinions and possibly biased if some key stakeholders are under-represented (Mehnen et al. 2013).
Case studies	It is not feasible, necessary, or desirable to assess effectiveness nationwide or worldwide but in specific cases	As per left	Case studies per se cannot directly assess effectiveness but need to integrate other categories of approaches.
Approaches focusing on a specific aspect of PAs	Assessors focus on a specific aspect of PAs	As per left	Theses approaches do not assess PAs' comprehensive effectiveness.

## 477           **4.2.           Implications for future research**

478   This review does not detail step-by-step instructions of the approaches or indicators. Indicators  
479   are standard units that express amount, size, level, or degree based on verifiable data  
480   (Biodiversity Indicators Partnership 2011), and are essential to effectiveness assessment.  
481   However, sample indicators for PA’s effectiveness can be found from Leverington et al. (2010)  
482   and CBD (2020b). We call for development of an expanded assessment guidebook integrating  
483   detailed instructions of the approaches and potential indicators that allow aggregation of  
484   estimates of effectiveness at local, national, regional, and global levels and promote  
485   understanding of PAs’ effectiveness at different levels to facilitate policy intervention.

486   Since developing theories of change can be challenging, we anticipate the development of a  
487   “theory toolkit” containing comprehensive theories of changes that are commonly accepted  
488   and directly applicable to evaluation of PAs’ effectiveness. Moreover, assessors may lack the  
489   knowledge to construct control groups for quasi-experimental designs, although the existing  
490   literature already provides many references for using different techniques (e.g., IV, DID) to  
491   construct control groups. Therefore, we do not expect additional guidance of using the existing  
492   techniques to construct control groups. Instead, we anticipate development of new control-  
493   group-constructing techniques that are more practical but still scientifically sound. We also  
494   anticipate more sophisticated and reliable techniques valuing ESs and biodiversity to become  
495   feasible to improve accuracy and credibility of PAs’ value estimates. Further research is also  
496   needed to distinguish the features (e.g., strengths, limitations) of different evaluation sheets for  
497   rapid assessments.

## 498           **4.3.           Linkage with global initiatives**

499   The CBD’s national reports require the CBD Parties to indicate the effectiveness of their PAs  
500   and explain how they assesses the effectiveness. However, in the latest (sixth) national reports,  
501   many Parties tended to assess the effectiveness based on simple observations (e.g., changes in  
502   winter bird counts) or subjective consideration (e.g., experts’ opinions). Therefore, this review  
503   may be beneficial for the Parties to improve the comprehensiveness of future effectiveness  
504   assessments.

505   Moreover, PAs are already integrated into targets or goals (Table 6) of several widely accepted  
506   global initiatives, including: (1) Sustainable Development Goals (SDGs) adopted by all United  
507   Nations member states (United Nations 2022), (2) CBD Post-2020 GBF that attempts to

508 mitigate and reverse biodiversity loss (CBD 2021), (3) United Nations Convention to Combat  
 509 Desertification (UNCCD) 2018-2030 Strategic Framework committed to avoid, minimise, and  
 510 reverse land degradation and mitigate drought effects (UNCCD 2017), and (4) Paris Agreement  
 511 committed to strengthen the global response to climate change (UNFCCC 2015). Details of the  
 512 PA-related targets or goals, as well as potential approaches for assessing effectiveness of the  
 513 actions taken to achieve them, are presented in Appendix 1.

514 **Table 6:** PA-related goals/targets in global initiatives

Initiatives	Goals or targets
SDGs	Target 6.6 of Goal 6, Targets 14.2 and 14.5 of Goal 14, Targets 15.1, 15.4 and 15.a of Goal 15
CBD Post-2020 GBF	Goals B and C Targets 3, 4, and 10
UNCCD 2018-2030 Strategic Framework	Target 4.1
Paris Agreement	Article 5

515 **Source:** (CBD 2021; UNCCD 2017; UNFCCC 2015; United Nations 2022)

516 **Note:** While the other goals and targets may be linked with PAs in some ways, this table only presents those  
 517 explicitly related to PAs or nature conservation.

518 The Post-2020 GBF has particularly strong connection with PAs and highlights (1)  
 519 improvement of ecosystem integrity, productivity, resilience, ecological representativeness,  
 520 ESs, information, and financial, technical, and human resources; (2) reduction of human-  
 521 wildlife conflicts, incentives harming biodiversity, impacts from invasive species, climate  
 522 change, and pollution, and threats to health of humans and other species; (3) promotion of  
 523 sustainability and fairness of access to, sharing, and use of genetic resources and other benefits;  
 524 and (4) effective participation in decision making. Effectiveness assessment may be conducted  
 525 on these aspects.

## 526 **5. Conclusion**

527 This review presents a quick and basic overview of a comprehensive set of approaches,  
 528 discusses their suitability to assist with selecting them, suggests future research for improving  
 529 their applicability, and outlines their linkage with some major global PA-related initiatives.  
 530 Effectiveness assessments are crucial to understanding whether and why PAs are working or  
 531 not, whether or which alternative PA-related actions are economically desirable, and how to

532 improve PAs' quality. Basic assessment approaches include (1) evaluation based on a theory  
533 of change that explains how and why interventions are supposed to deliver anticipated results;  
534 (2) counterfactual evaluation that uses a random control group, a control group constructed  
535 through several techniques, or a baseline of the treatment group as the counterfactual; (3)  
536 economic valuation that assesses benefits and costs of an intervention; (4) consultation; (5)  
537 case studies; (6) rapid assessments based on readily available evaluation sheets; and (7)  
538 approaches focusing on a specific aspect, such as conservation enforcement, ecological  
539 integrity, species representativeness, and anthropogenic threats.

540 The approaches have different characteristics and should be selected in accordance with  
541 assessment purposes, data availability, budgets, and assessors' expertise. Theory-based  
542 evaluation is integral to all assessments. Assessments involving comparison can apply  
543 counterfactual evaluation, especially quasi-experimental designs that are often more practical  
544 than experimental designs and more credible than non-experimental designs. Economic  
545 valuation addresses if an intervention is economical. Consultation is based on second-hand  
546 knowledge. Case studies should be combined with other approaches. Evaluation sheets for  
547 rapid assessments may be convenient but lack distinct features of how they differ from each  
548 other. Approaches focusing on a specific aspect cannot assess PAs' comprehensive  
549 effectiveness.

550 For future research, we anticipate (1) an expanded assessment guidebook integrating detailed  
551 instructions of the approaches, (2) new control-group-constructing techniques that are more  
552 practical but still scientifically sound, (3) more sophisticated and reliable ES valuation  
553 techniques, and (4) further work to distinguish the features of different evaluation sheets for  
554 rapid assessments. This review also potentially benefits preparation of the CBD Parties'  
555 National Reports (that require information on PAs' effectiveness) and evaluation of actions  
556 taken to fulfill PA-related goals or targets of global initiatives, including the SDGs, CBD Post-  
557 2020 GBF, UNCCD 2018-2030 SF, and Paris Agreement. PAs' effectiveness assessment can  
558 pay particular attention to the Post-2020 GBF, which highlights a set of aspects of outcomes  
559 and management of PAs.

## 560 **Acknowledgement**

561 This research did not receive any specific grant from funding agencies in the public,  
562 commercial, or not-for-profit sectors. We thank the Convention on Biological Diversity

563 Secretariat for constructive suggestions. We also thank the journal editor and reviewers for  
564 valuable comments.
