NICE has accredited the process used by BSR to create its clinical guidelines. The term began on 27 February 2012 and the current renewed accreditation is valid until 31 December 2023. More information on accreditation can be viewed at www.nice.org.uk/accreditation.

Scope and purpose

Need for guideline

The rationale behind this update of the 2016 British Society for Rheumatology (BSR) guidelines on prescribing anti-rheumatic drugs in pregnancy and breastfeeding [1, 2] was previously described [3]. Additional evidence-based guidelines on managing rheumatic disease in pregnancy now exist [4–7]. However, emerging information on pregnancy exposures to biologic DMARDs, biosimilars and targeted synthetic DMARDs requires regular review to assess their safety in pregnancy. Uncertainty around use of these drugs in pregnancy may lead to withdrawal of treatment from women with inflammatory rheumatic diseases (IRDs) unnecessarily [8], which can increase the risk of poor disease control during pregnancy [9].

Data from Mothers and Babies: Reducing Risk through Audits and Confidential Enquiries across the UK (MBRRACE-UK) between 2017 and 2019 found that 8.8 women per 100 000 died during pregnancy or up to six weeks after childbirth or the end of pregnancy, and most women who died had multiple health problems or other vulnerabilities [10]. In all decisions regarding medication choices and changes, it is important to consider the potential for deterioration in the mother’s wellbeing through side effects or reduced disease control (and its adverse impact on the baby) [10]. As such, the potential benefit to the foetus from any drug changes in the mother must be balanced against the possible risks to the foetus from loss of disease control in the mother [11].

Objectives of guideline

To update the previous BSR guidelines on prescribing in pregnancy in rheumatic disease of corticosteroids and immunomodulatory drugs (Supplementary Data S1, available at Rheumatology online) by systematically reviewing all evidence published since the previous guideline.

This guideline will highlight medications that should be stopped and/or avoided in the reproductive age group unless highly effective contraception is used, in line with guidance issued by the Medicines and Healthcare Products Regulatory Agency and the Faculty of Sexual and Reproductive Healthcare [12, 13].

Target audience

This guideline is directed at healthcare professionals in the UK involved in managing patients with rheumatic disease who are (or are planning to become) pregnant and/or breastfeeding, men with rheumatic disease who are planning to conceive, and patients with rheumatic disease who have unintentionally conceived while taking these medications. This audience includes rheumatologists, nurses/allied health professionals, rheumatology specialty trainees and pharmacists, as well as the patients themselves. The guideline will also be useful to obstetricians, obstetric physicians, midwives, renal physicians, dermatologists, gastroenterologists, respiratory physicians and general practitioners who prescribe these medications in pregnancy.

This guideline uses the terms ‘woman’, ‘maternal’ or ‘mother’ throughout. These should be taken to include people who do not identify as women but are pregnant or have given birth [14]. Where the term ‘breastfeeding’ is used in this guideline it also refers to infant breastmilk exposure via other methods (e.g. expressed breastmilk, administered via a bottle).

The areas the guideline does not cover

This guideline does not cover the management of infertility or the indications for these drugs in rheumatic diseases in pregnancy. Other drug categories (pain management; non-steroidal anti-inflammatory drugs and low dose aspirin; anticoagulants; bisphosphonates; anti-hypertensives; and pulmonary vasodilators) are considered in the BSR guideline on prescribing drugs in pregnancy and breastfeeding: comorbidity medications used in rheumatology practice [15]. All recommendations in this guideline were formulated by the working group on the basis of published evidence at the time of the systematic literature search, and do not necessarily refer to licencing information or Summary of Product Characteristics for individual medications.

Stakeholder involvement

A guideline working group (GWG), chairman of the BSR, consisted of rheumatologists from a range of clinical backgrounds, allied health professionals, other specialists in women’s health, lay members, and representatives from the United Kingdom Teratology Information Service (UKTIS), this is shown in Supplementary Table S1, available at Rheumatology online.

Rigour of development

Statement of scope of literature search and strategy employed

Evidence used to develop these guidelines was compiled from a systematic literature search conducted according to guidelines of Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) [16]. Studies were identified by searching MEDLINE and Embase databases from 1 January 2014 to 31 December 2020, with additional studies identified through the Cochrane, LactMed and UKTIS databases (Supplementary Data S2, available at Rheumatology online). The searches were conducted in January 2021. Limits were placed for English language studies. The searches were not limited by disease indication; studies in non-rheumatic diseases were considered, if relevant. Evidence from the current searches (referred to as ‘recent studies’ in the text) was combined with data from the previous guideline (referred to as ‘previous studies’) [1], to inform recommendations. Relevant pharmaceutical companies were also contacted for additional data.

Two independent reviewers screened the titles and abstracts of articles, reviewed the full texts of studies that met inclusion criteria (Supplementary Data S2, available at Rheumatology online), and performed data extraction. Any disagreements were resolved by group discussion.

Statement of methods used to formulate the recommendations (levels of evidence)

This guideline was developed in line with BSR’s Guidelines Protocol using Grading of Recommendations, Assessment, Development and Evaluations (GRADE) methodology, to determine quality of evidence and strength of recommendation. Accompanying each recommendation, in brackets, is the strength of recommendation, quality of evidence and strength of agreement (SOA).

Recommendations were categorized as strong (1), when the benefits clearly outweigh the risks (or vice versa), or weak (2),
when the benefits were more closely balanced with the risks or more uncertain. The quality of evidence was determined as high (A), moderate (B) or low/very low (C), reflecting the confidence in the estimates of benefits or harm. The wording of each recommendation was agreed by all members and subjected to a vote for SOA on a scale of 1–100 (no to complete agreement). The guideline will be updated in five years.

The guideline

A flow diagram of study selection is shown in Fig. 1. The findings for all drug exposures, including information from the previous BSR guideline [1], are summarized in the full-length guideline. An overall summary of the compatibility of each drug pre-conception, during pregnancy, with breastmilk exposure, and with paternal exposure is shown in Table 1. For each drug, maternal information is summarized in Tables 2 and 3, while paternal information is summarized in Table 4. The data synthesis strategy for Tables 2–4 is shown in Supplementary Data S3, available at Rheumatology online. The list of references included within the evidence tables is shown in Supplementary Data S4, also available at Rheumatology online.

Generic recommendations on prescribing immunomodulatory drugs and/or corticosteroids in rheumatic disease in pregnancy

i) Pre-conception counselling should be addressed by all healthcare professionals, with referral to professionals with relevant expertise as appropriate, to optimize disease control before pregnancy; with advice on the timing of pregnancy, and drug therapy before, during and after pregnancy, including contraception (GRADE 1A, SOA 99.5%).

ii) If a woman is planning pregnancy, avoid pregnancy-incompatible drugs (GRADE 1A, SOA 100%).

iii) The risks and benefits to the mother and foetus of drug treatment to control maternal disease should be discussed and clearly documented by all healthcare professionals involved in the patient’s care (GRADE 1A, SOA 99.5%).

iv) Immunomodulatory drugs that are contraindicated in pregnancy should be switched to a pregnancy-compatible alternative in advance of conception to ensure maintenance of disease control on the new medication (GRADE 1A, SOA 100%).

v) When no pregnancy-compatible drugs are suitable, control of severe/life-threatening maternal disease should take priority over concerns for potential foetal outcomes (GRADE 1B, SOA 99.0%).

vi) All biologic DMARDs may be continued throughout pregnancy if required to control active/severe maternal disease (GRADE 1B, SOA 98.5%).

vii) Immunisation schedules in infants after in-utero exposure to biologic DMARDs will depend on timing of exposure, bioavailability and persistence of the drug, mechanism of action of the drug, and live vaccines (GRADE 1C, SOA 99.5%).

viii) Where possible, the minimum effective dose of immunomodulatory drug or corticosteroid should be used to maintain maternal disease suppression, and stopping the drug during pregnancy may be considered in women at low risk of disease flare on withdrawal of therapy (GRADE 1B, SOA 100%).

ix) Some drugs may reduce male fertility, but paternal drug exposure in humans has not convincingly been associated with adverse foetal development or pregnancy outcome. Although the evidence is weak, men who take rheumatological medicines should be reassured about the safety of conceiving (GRADE 2C, SOA 98.4%).

Antimalarials

Recommendations were based on 23 studies of HCQ identified in the current literature search and 23 studies identified in the previous guideline’s literature search, in addition to four studies of chloroquine and no studies of mepacrine. Three recent and one previous study of breastmilk exposure to HCQ were identified.

Recommendations for hydroxychloroquine in pregnancy and breastmilk exposure

i) HCQ remains the antimalarial of choice in women planning a pregnancy with rheumatic disease in need of treatment, and should be continued during pregnancy at dose of ≤400 mg/day (GRADE 1B, SOA 100%).

ii) HCQ is compatible with breastmilk exposure (GRADE 1B, SOA 99.5%).

Corticosteroids

Recommendations were based on 11 recent studies of prednisolone, one study of methylprednisolone, and previous studies: 47 on prednisolone; 31 on dexamethasone; 27 on betamethasone; and 10 on general corticosteroid use.

Recommendations for corticosteroids in pregnancy and breastmilk exposure

i) Prednisolone is compatible with pregnancy and is the preferred corticosteroid in the treatment of maternal rheumatological disease in pregnancy and requires shared care with obstetric teams to monitor maternal blood pressure and blood glucose (GRADE 1B, SOA 100%).

</table>

For further information and caveats, see relevant recommendations and main text in the executive summary and full guideline.

- In the healthy, full-term infant only.
- If conception is delayed by >12 months, consider stopping sulfasalazine alongside investigation of other causes of infertility.
- Only in cases of severe (life or organ-threatening) maternal disease.
- If low risk of disease flare and stopped by 32 weeks, full term infant can have a normal vaccination schedule.
- Limited evidence.

</table>

All studies that provided quantitative and/or qualitative information on the safety of the relevant drug in pregnancy were included; however, numerical outcome data could only be collated from papers where the relevant outcome was clearly quantified. Details of how numerical data in this table were derived are shown in Supplementary Data S3, available at *Rheumatology* online. References shown in the table are included within Supplementary Data S4, available at *Rheumatology* online. cc: case control; Cochr: Cochrane review; cr: case report; cs: case series; CsA: ciclosporin; ct: cohort; MP: methylprednisolone; NR: not reported; nrt: non-randomized trial; Pred: prednisolone; rct: randomised controlled trial; SOA: strength of agreement; sr: systematic review; TAC: tacrolimus.

| UST  | 2 ct [254, 255] 1 cs [256] | 517 (1st ≥31, 2nd/3rd ≥10) | 92/517 | No significant adverse effect noted | 17/375 | i) Limited evidence has not shown UST to be teratogenic; however, there remains insufficient evidence to be confident that it is compatible with pregnancy. Consider stopping the drug at conception. Any exposure, however, during pregnancy is unlikely to be harmful (GRADE 2C, SOA 99.3%)  
ii) UST may be considered to manage severe maternal disease in pregnancy if no other pregnancy-compatible drugs are suitable (GRADE 2C, SOA 98.8%)  
iii) If UST is used to treat severe maternal disease in the third trimester, it is currently recommended to avoid all live vaccines in the infant vaccination schedule until 6 months of age (GRADE 2C, SOA 99.3%)  
iv) Based on limited evidence, maternal treatment with UST is compatible with breastfeeding exposure (GRADE 2C, SOA 99.5%) |
| TOF  | 1 ct [257] | 116 (all 1st, 2nd/3rd NR) | 15/72 | No significant adverse effect noted | 2/44 | i) There are insufficient data to make a recommendation on JAKi use during pregnancy and they should be stopped at least two weeks before planned conception (GRADE 2C, SOA 99.5%)  
ii) There are insufficient data to recommend JAKi in breastfeeding and, given they are likely to transfer into breast milk, they should be avoided (GRADE 2C, SOA 99.5%) |

All studies that provided quantitative and/or qualitative information on the safety of the relevant drug in pregnancy were included; however, numerical outcome data could only be collated from papers where the relevant outcome was clearly quantified. Details of how numerical data in this table were derived are shown in Supplementary Data S3, available at Rheumatology online. References shown in the table are included within Supplementary Data S4, available at Rheumatology online.

ABA: abatacept; ADA: adalimumab; ANA: anakinra; BEL: belimumab; CAN: canakinumab; cc: case control; cr: case report; cs: case series; ct: cohort; CZP: certolizumab; ETA: etanercept; GOL: golimumab; IL-1i: IL-1 inhibitors; IL-6i: IL-6 inhibitors; IL-17i: IL-17 inhibitors; INF: infliximab; IXE: ixekizumab; JAKi: Janus kinase inhibitor; NR: not reported; rct: randomized controlled trial; RTX: rituximab; SEC: secukinumab; SOA: strength of agreement; TNFi: TNF-alpha inhibitor; TOC: tocilizumab; TOF: tofacitinib; UST: ustekinumab.
Where possible, the dose of prednisolone should be <20 mg/day and tapered to the minimum effective dose to control maternal disease, in conjunction with steroid-sparing drugs compatible with pregnancy (GRADE 1C, SOA 99.5%).

Prednisolone is compatible with breastfeeding exposure (GRADE 1B, SOA 100%).

Methylprednisolone has similar rates of placental transfer to prednisolone and would therefore be expected to be compatible with pregnancy and breastfeeding exposure (GRADE 2C, SOA 99%).

**Conventional synthetic DMARDs**

**Methotrexate**

Recommendations were based on 12 recent and 10 previous studies of MTX.
Recommendations for methotrexate in pregnancy and breastmilk exposure

i) MTX at any dose should be avoided in pregnancy and stopped at least one month in advance of planned conception, when it should be switched to another pregnancy-compatible drug to ensure maintenance of maternal disease suppression (GRADE 1A, SOA 98%).

ii) In women treated with low-dose (≤25 mg/week) MTX within one month prior to conception, folic acid supplementation (5 mg/day) should be continued up to 12 weeks of pregnancy (GRADE 1B, SOA 99.5%).

iii) In unintended pregnancy on low-dose (≤25 mg/week) MTX, there is minimal risk to the foetus; the drug should be stopped immediately, folic acid supplementation (5 mg/day) continued, and a careful evaluation of foetal risk with early referral to a foetal medicine department considered (GRADE 1C, SOA 100%).

iv) Although only minute amounts of MTX are excreted into breastmilk, MTX cannot be recommended in breastfeeding because of theoretical risks and insufficient data on outcomes (GRADE 2C, SOA 99%).

Sulphasalazine
Recommendations were based on six studies of SSZ identified in the previous guideline.

Recommendations for sulphasalazine in pregnancy and breastmilk exposure

i) SSZ is compatible throughout pregnancy, with folic acid 5 mg/day recommended in the periconception period and during the first trimester (GRADE 1B, SOA 100%).

ii) SSZ is compatible with breastmilk exposure in healthy, full-term infants (GRADE 1C, SOA 99.5%).

Leflunomide
Recommendations were based on three recent and seven previous studies of LEF.

Recommendations for leflunomide in pregnancy and breastmilk exposure

i) LEF may not be a human teratogen but there remains insufficient evidence to support use at the time of conception or during pregnancy (GRADE 1B, SOA 98%).

ii) Women on LEF considering pregnancy should stop and undergo a standard cholestyramine washout procedure, and switch to alternative medication compatible with pregnancy (GRADE 1B, SOA 98.8%).

iii) If unintended conception occurs on LEF, the drug should be stopped immediately and a standard cholestyramine washout procedure given, with early referral to a foetal medicine department considered (GRADE 1B, SOA 99%).

iv) LEF is not recommended while breastfeeding (GRADE 1C, SOA 99.5%).

Azathioprine
Recommendations were based on nine recent and 28 previous studies of AZA.

Recommendations for azathioprine in pregnancy and breastmilk exposure

i) AZA is compatible throughout pregnancy (GRADE 1B, SOA 100%).

ii) AZA is compatible with breastmilk exposure (GRADE 2C, SOA 99.5%).

Ciclosporin
Recommendations were based on five recent and 13 previous studies of ciclosporin (CsA).

Recommendations for ciclosporin in pregnancy and breastmilk exposure

i) CsA is compatible throughout pregnancy with monitoring of maternal blood pressure, renal function, blood glucose and drug levels (GRADE 1B, SOA 100%).

ii) CsA is compatible with breastmilk exposure (GRADE 2C, SOA 99.7%).

Tacrolimus
Recommendations were based on eight recent and seven previous studies of tacrolimus.

Recommendations for tacrolimus in pregnancy and breastmilk exposure

i) Tacrolimus is compatible throughout pregnancy with monitoring of maternal blood pressure, renal function, blood glucose and drug levels (GRADE 2B, SOA 100%).

ii) Tacrolimus is compatible with breastmilk exposure (GRADE 2C, SOA 99.8%).

Cyclophosphamide
Recommendations were based on one recent and five previous studies of CYC.

Recommendations for cyclophosphamide in pregnancy and breastmilk exposure

i) CYC is a known teratogen and gonadotoxic, and therefore should only be considered in pregnancy in cases of severe life/organ-threatening maternal disease when there is appreciable risk of maternal and foetal morbidity and mortality without this therapy (GRADE 1B, SOA 99.5%).

ii) CYC is not recommended while breastfeeding (GRADE 2C, SOA 100%).

Mycophenolate mofetil
Recommendations were based on eight recent and 16 previous studies of MMF.

Recommendations for mycophenolate mofetil in pregnancy and breastmilk exposure

i) MMF remains contraindicated during pregnancy, and should be avoided in women planning pregnancy or switched to a pregnancy-compatible alternative at least 6 weeks before attempting to conceive (GRADE 1B, SOA 100%).
In cases of unintended conception, switch MMF to a pregnancy-compatible alternative and refer to local experts for further advice and risk assessment (GRADE 1B, SOA 100%).

MMF is not recommended while breastfeeding (GRADE 2C, SOA 99.7%).

**Intravenous immunoglobulin**

Two recent and 16 previous studies of IVIG were identified.

**Recommendations for intravenous immunoglobulin in pregnancy and breastmilk exposure**

i) IVIG is compatible with pregnancy (GRADE 1B, SOA 99.5%).

ii) IVIG is compatible with breastmilk exposure (GRADE 2C, SOA 100%).

**Biologic DMARDs**

**Anti-TNFα drugs**

Recommendations were based on 50 recent studies, two breastmilk transfer studies, and 29 previous studies of tumour necrosis factor-α inhibitors (TNFi).

**Recommendations for anti-TNFα medications in pregnancy and breastmilk exposure**

i) Women with no/low disease activity established on a TNFi with known placental transfer [infliximab (INF), adalimumab (ADA), golimumab (GOL)] do not need to be switched to an alternative TNFi with established minimal placental transfer [certolizumab pegol (CZP)] either before or during pregnancy (GRADE 1B, SOA 100%).

ii) CZP is compatible with all three trimesters of pregnancy, has no to minimal placental transfer compared with other TNFi, and does not require any alteration to the infant vaccination schedule (GRADE 1B, SOA 100%).

iii) Women considered to have low risk of disease flare on withdrawal of TNFi in pregnancy could stop INF at 20 weeks, ADA and GOL at 28 weeks, and ETA at 32 weeks so that a full-term infant can have a normal vaccination schedule, with rotavirus vaccination at 8 weeks as per the UK schedule (GRADE 1B, SOA 99.5%).

iv) INF, ADA, ETA or GOL may be continued throughout pregnancy to maintain maternal disease control; in these circumstances, live vaccines should be avoided in infants until they are 6 months of age (GRADE 1B, SOA 100%).

v) If a TNFi is stopped in pregnancy, it can be restarted as soon as practical post-partum in the absence of infections or surgical complications, regardless of breastfeeding status, to ensure control of maternal disease (GRADE 1C, SOA 100%).

vi) TNFi are compatible with breastmilk exposure (GRADE 1C, SOA 100%).

**Rituximab**

Recommendations were based on five recent studies, a breastmilk transfer study, and eight previous studies of rituximab (RTX).

**Recommendations for rituximab in pregnancy and breastmilk exposure**

i) Limited evidence has not shown RTX to be teratogenic; however, there remains insufficient evidence to be confident that it is compatible with pregnancy. Consider stopping the drug at conception (GRADE 2C, SOA 99.3%).

ii) RTX may be considered to manage severe maternal disease in pregnancy if no other pregnancy-compatible drugs are suitable (GRADE 2C, SOA 99.7%).

iii) If RTX is used to treat severe maternal disease in the third trimester, it is currently recommended to avoid all live vaccines in the infant vaccination schedule until 6 months of age (GRADE 2C, SOA 98.7%).

iv) Based on limited evidence, maternal treatment with RTX is compatible with breastmilk exposure (GRADE 2C, SOA 99.5%).

**Interleukin-6 inhibitors**

We identified three recent studies and one previous study of tocilizumab (TCZ). No studies of sarilumab were identified.

**Recommendations for IL-6 inhibitors in pregnancy and breastmilk exposure**

i) Limited evidence has not shown IL-6 inhibitors (IL-6i) to be teratogenic; however, there remains insufficient evidence to be confident that they are compatible with pregnancy. Consider stopping the drug at conception. Any exposure, however, during pregnancy is unlikely to be harmful (GRADE 2C, SOA 99.7%).

ii) IL-6i may be considered to manage severe maternal disease in pregnancy if no other pregnancy-compatible drugs are suitable (GRADE 2C, SOA 100%).

iii) If IL-6i are used to treat severe maternal disease in the third trimester, it is currently recommended to avoid all live vaccines in the infant vaccination schedule until 6 months of age (GRADE 2C, SOA 99.3%).

iv) Based on limited evidence, maternal treatment with IL-6i is compatible with breastmilk exposure (GRADE 2C, SOA 100%).

**Interleukin-1 inhibitors**

We identified four recent and three previous studies of anakinra and one study of canakinumab.

**Recommendations for IL-1 inhibitors in pregnancy and breastmilk exposure**

i) Limited evidence has not shown IL-1 inhibitors (IL-1i) to be teratogenic; however, there remains insufficient evidence to be confident that they are compatible with pregnancy. Consider stopping the drug at conception. Any exposure, however, during pregnancy is unlikely to be harmful (GRADE 2C, SOA 99.8%).

ii) IL-1i may be considered to manage severe maternal disease in pregnancy if no other pregnancy-compatible drugs are suitable (GRADE 2C, SOA 100%).

iii) If IL-1i are used to treat severe maternal disease in the third trimester, it is currently recommended to avoid all...
live vaccines in the infant vaccination schedule until 6 months of age (GRADE 2C, SOA 99.3%).

iv) Based on limited evidence, maternal treatment with IL-1i is compatible with breastmilk exposure (GRADE 2C, SOA 100%).

Abatacept
We identified two recent and three previous studies of abatacept (ABA).

Recommendations for abatacept in pregnancy and breastmilk exposure

i) Limited evidence has not shown ABA to be teratogenic; however, there remains insufficient evidence to be confident that it is compatible with pregnancy. Consider stopping the drug at conception. Any exposure, however, during pregnancy is unlikely to be harmful (GRADE 2C, SOA 99.3%).

ii) ABA may be considered to manage severe maternal disease in pregnancy if no other pregnancy-compatible drugs are suitable (GRADE 2C, SOA 99.3%).

iii) If ABA is used to treat severe maternal disease in the third trimester, it is currently recommended to avoid all live vaccines in the infant vaccination schedule until 6 months of age (GRADE 2C, SOA 99.3%).

iv) Based on limited evidence, maternal treatment with ABA is compatible with breastmilk exposure (GRADE 2C, SOA 99.5%).

Belimumab
We identified one recent and two previous studies of belimumab (BEL).

Recommendations for belimumab in pregnancy and breastmilk exposure

i) Limited evidence has not shown BEL to be teratogenic; however, there remains insufficient evidence to be confident that it is compatible with pregnancy. Consider stopping the drug at conception. Any exposure, however, during pregnancy is unlikely to be harmful (GRADE 2C, SOA 99.3%).

ii) BEL may be considered to manage severe maternal disease in pregnancy if no other pregnancy-compatible drugs are suitable (GRADE 2C, SOA 99.5%).

iii) If BEL is used to treat severe maternal disease in the third trimester, it is currently recommended to avoid all live vaccines in the infant vaccination schedule until 6 months of age (GRADE 2C, SOA 99.3%).

iv) Based on limited evidence, maternal treatment with BEL is compatible with breastmilk exposure (GRADE 2C, SOA 99.5%).

Interleukin-17 inhibitors
We identified three studies of secukinumab and ixekizumab.

Recommendations for interleukin-17 inhibitors in pregnancy and breastmilk exposure

i) Limited evidence has not shown interleukin-17 inhibitors (IL-17i) to be teratogenic; however, there remains insufficient evidence to be confident that they are compatible with pregnancy. Consider stopping the drug at conception. Any exposure, however, during pregnancy is unlikely to be harmful (GRADE 2C, SOA 99.3%).

ii) IL-17i may be considered to manage severe maternal disease in pregnancy if no other pregnancy-compatible drugs are suitable (GRADE 2C, SOA 99.9%).

iii) If IL-17i are used to treat severe maternal disease in the third trimester, it is currently recommended to avoid all live vaccines in the infant vaccination schedule until 6 months of age (GRADE 2C, SOA 99.3%).

iv) Based on limited evidence, maternal treatment with IL-17i is compatible with breastmilk exposure (GRADE 2C, SOA 99.5%).

Anifrolumab
Anifrolumab was not NICE approved at the time of our literature search, and so was not included in the search.

Targeted synthetic DMARDs

Apremilast
No studies relating to apremilast use in pregnancy were found.

JAK inhibitors
We identified three studies of tofacitinib (TOF) and no studies of baricitinib or upadacitinib. Filgotinib was NICE approved after our search, and so was not included.

Recommendations for JAK inhibitors in pregnancy and breastmilk exposure

i) There are insufficient data to make a recommendation on Janus kinase inhibitor (JAKi) use during pregnancy and they should be stopped at least two weeks before planned conception (GRADE 2C, SOA 99.5%).

ii) There are insufficient data to recommend JAKi in breastfeeding and, given they are likely to transfer into breastmilk, they should be avoided (GRADE 2C, SOA 99.5%).
Paternal exposure

Recommendations for paternal exposure to immunomodulatory drugs

i) Due to the adverse effect of CYC on male fertility, semen cryopreservation is recommended for men prior to paternal exposure (GRADE 1C, SOA 99.5%).

ii) Men who take SSZ may have reduced fertility. There is little evidence to suggest that SSZ should be stopped pre-conception, unless conception is delayed by more than 12 months when stopping SSZ should be considered along with other causes of infertility (GRADE 1C, SOA 99.0%).

iii) Paternal exposure to the following anti-rheumatic medication is compatible with pregnancy: prednisolone, low-dose (≤25 mg/week) methotrexate, azathioprine (GRADE 1B); TNFi, cyclosporin (GRADE 1C); hydroxychloroquine, leflunomide, tacrolimus, mycophenolate mofetil, intravenous immunoglobulin, rituximab, interleukin-6 inhibitors, interleukin-1 inhibitors, abatacept, belimumab, interleukin-17 inhibitors, ustekinumab and JAKi (GRADE 2C, SOA 99.3%).

Applicability and utility

Implementation

Awareness of these guidelines will aid clinical practitioners and patients in decision making. No barriers to implementation of these guidelines are anticipated.

Key standards of care

Patients with rheumatic disease should receive pre-pregnancy counselling and regular review during pregnancy and for 6 months post-partum by clinical practitioners with expertise in the management of rheumatic disease in pregnancy. They should have access to information on relevant medications in pregnancy and breastfeeding, enabling them to make informed decisions on drug use in pregnancy.

Future research agenda

Research questions include: should biologic DMARDs with known placental transfer be stopped or switched before/during pregnancy; are targeted synthetic DMARDs compatible with pregnancy; is it safe to give certain live vaccines to infants ≤6 months of age after third trimester exposure to biologic DMARDs with high placental transfer?

Mechanism for audit of the guideline

An audit tool to assess compliance with these guidelines is shown in Supplementary Data S5, available at Rheumatology online.

Supplementary data

Supplementary data are available at Rheumatology online.

Data availability statement

All relevant data produced during the guideline development process are presented in the guideline or in the accompanying supplementary material.

Funding

No specific funding was received from any bodies in the public, commercial or not-for-profit sectors to carry out the work described in this manuscript.

Disclosure statement: All authors have made declarations of interest in line with BSR policy (see Supplementary Material, available at Rheumatology online). L.M. has received honoraria from UCB and educational funding support from Abbvie and Pfizer. C.G. has received honoraria from Abbvie, Alums, Amygen, Astra-Zeneca, MGP, Sanofi and UCB. C-S.Y. has received honoraria from Amygen. K.Sc has received educational support from UCB and honoraria from UCB and Thermo-Fisherworks and Novo Nordic Foundation research grant. L.W. has received honorarium from Novartis. M.D.R. has received educational funding support from Lilly, Pfizer, Janssen and UCB and honoraria from Lilly, Menarini and Biogen. S.T. has received honoraria from UCB. I.G. has received honoraria and unrestricted research grants from UCB. K.H. has received honoraria and educational support from UCB. M.G. has received honoraria from UCB, Lilly and Abbvie. M.K. is an employee of GSK and gave independent expert advice to the Working Group. The remaining authors have declared no conflicts of interest.

Acknowledgements

A full list of Standards, Audit and Guidelines Working Group members can be found in Supplementary Data S6, available at Rheumatology online. All contributing members are named in the authorship list.
