## ABSTRACT

Bound states of the $\mathrm{He}_{2}$ molecule are determined from an electron $-\mathrm{He}_{2}^{+}$collision calculation using the R-matrix method. The calculations are performed at a moderately dense grid of 35 internuclear separations are used to characterise $\mathrm{He}_{2}$ Rydberg states with $n \leq 7$. Potential energy curves for singlet ${ }^{1} \Sigma_{g}^{+},{ }^{1} \Sigma_{u}^{+},{ }^{1} \Pi_{g},{ }^{1} \Pi_{u}$ and ${ }^{1} \Delta_{u}$ and triplet ${ }^{3} \Sigma_{g}^{+},{ }^{3} \Sigma_{u}^{+},{ }^{3} \Pi_{g},{ }^{3} \Pi_{u}$ and ${ }^{3} \Delta_{u}$ Rydberg states of $\mathrm{He}_{2}$ as well as effective quantum numbers as a function of internuclear separation are calculated. Based on the potential energy curves of $\mathrm{A}^{1} \Sigma_{g}^{+}, \mathrm{B}^{1} \Pi_{g}, \mathrm{C}^{1} \Sigma_{u}^{+}, \mathrm{F}^{1} \Pi_{u}$ and a ${ }^{3} \Sigma_{u}^{+}, \mathrm{b}^{3} \Pi_{g}, \mathrm{C}^{3} \Sigma_{g}^{+}, \mathrm{f}^{3} \Pi_{u}$, spectroscopic parameters ( $T_{e}, D_{e}, R_{e}, \omega_{e}, \omega_{e} X_{e}, \alpha_{e}$ and $B_{e}$ ) of these states have been determined and compared with theoretical and experimental data available.

Helium dimer; rydberg states; quantum defects

## 1. Introduction

$\mathrm{He}_{2}$ was the first excimer (excited dimer) to be discovered and is an example of a Rydberg molecule [1]. Its ground state $\mathrm{X}^{1} \Sigma_{g}^{+}$is very shallow and the low-lying
excited states are Rydberg states formed by a diffuse electron orbiting an $\mathrm{He}_{2}^{+}$core. The ground state of the $\mathrm{He}_{2}$ molecule has been the subject of many works, particularly studies using high-level theory [2-7] for which it

[^0]has become a benchmark system. Electronically excited states of $\mathrm{He}_{2}$ have been the subject of some experimental and theoretical studies [8-11] but have not been treated in detail with the exception of some states which have been studied in the context of particular problems such as the determination of cross-section for Penning and associative ionisation from the potential energy curves for the ${ }^{1} \Sigma_{g}^{+}$and ${ }^{1} \Sigma_{u}^{+}$autoionising states [12], electric dipole transition moments and Einstein spontaneous emission coefficients for $\mathrm{X}^{1} \Sigma_{g}^{+} \rightarrow \mathrm{A}^{1} \Sigma_{u}^{+}$system [13].

The Rydberg states of the $\mathrm{He}_{2}$ molecule were first discovered in 1913 [14,15]. Since then, several calculations of bound states of $\mathrm{He}_{2}$ have been reported. Browne [16] computed the lowest ${ }^{1} \Sigma_{u}^{+},{ }^{3} \Sigma_{g}^{+}$and the first excited ${ }^{1} \Sigma_{g}^{+}$states of $\mathrm{He}_{2}$. A reasonable set of interatomic potential energy curves for a number of excited electronic
(Rydberg) states of $\mathrm{He}_{2}$ have been constructed using the Rydberg-Klein-Ress(RKR) procedure by Ginter and Battino [17]. The potential energy curve of the lowest singlet excited state $\mathrm{A}^{1} \Sigma_{u}^{+}$was calculated by Mukamel and Kaldor [18] and Komasa [13]. Cohen [8] obtained diabatic and adiabatic potential energy curves for the ${ }^{3} \Sigma_{g, u}^{+},{ }^{3} \Pi_{g, u},{ }^{3} \Delta_{g}$ triplet states. Sunil et al. [19] used the Unitary Group multiconfiguration self-consistent field (MCSCF) procedure to calculate the potential curves of $\mathrm{X}^{1} \Sigma_{g}^{+}, \mathrm{C}^{1} \Sigma_{g}^{+}, \mathrm{c}^{3} \Sigma_{g}^{+}, \mathrm{A}^{1} \Sigma_{u}^{+}, \mathrm{a}^{3} \Sigma_{u}^{+}$. Konowalow and Lengsfield [20] obtained from second-order configuration interaction calculations, the potential energy curves of ${ }^{3} \Sigma_{u}^{+}$states of $\mathrm{He}_{2}$ which correspond to the interactions of $\mathrm{He}\left(1 \mathrm{~s}^{2}{ }^{1} \mathrm{~S}\right)$ and $\mathrm{He}\left(1 \mathrm{~s} 2 \mathrm{~s}^{3} \mathrm{~S}\right)$, and $\mathrm{He}\left(1 \mathrm{~s} 2 \mathrm{~s}^{3} \mathrm{~S}\right)$ with $\mathrm{He}\left(1 \mathrm{~s} 2 \mathrm{~s}^{3} \mathrm{~S}\right)$. They also produced vibrational energy levels and their spacing for the a ${ }^{3} \Sigma_{u}^{+}$of ${ }^{4} \mathrm{He}_{2}$. The properties

${ }^{\text {a }}$ Experiment from Huber and Herzberg [9].
of the excited states of $\mathrm{He}_{2}$ have also been calculated by Yarkony [21]. Energies, effective quantum number and quantum defect for $\mathrm{He}_{2}\left(1 \sigma_{g}^{2} 1 \sigma_{u} \mathrm{~ns}\right.$, nd $\sigma$ and ng $\left.\sigma\right)$ bound state for ${ }^{3} \Sigma_{u}^{+}$state were performed using the R-matrix technique with a ( $4 \mathrm{~s}, 2 \mathrm{p}, 2 \mathrm{~d}$ ) Slater basis at full CI levels [22]. As indicated by Guberman [23], the ${ }^{3} \Sigma_{g}^{+}$and ${ }^{1} \Sigma_{g}^{+}$ states provide the main routes for dissociative recombination of $\mathrm{He}_{2}^{+}$, but other diabatic states of $\mathrm{He}_{2}$, such as ${ }^{3} \Pi_{u},{ }^{1} \Pi_{u},{ }^{3} \Sigma_{u}^{+}$and ${ }^{1} \Sigma_{u}^{+}$are also possible routes. In a previous study [24], we used the R-matrix method to characterise these dissociative resonant states of $\mathrm{He}_{2}$ and included consideration of these when they become bound at large internuclear separation. However, we did not study the Rydberg states of $\mathrm{He}_{2}$ which, amongst other things, play an important role in the dissociative recombination process.

The use of electron-molecular ion scattering wavefunctions has proved to be a powerful method of characterising Rydberg states which have been shown to be

results can be used for the calculation of cross-section and rate coefficients of dissociative recombination and related competitive processes, as well as interpretation of Rydberg state spectra.

## 2. Calculations

### 2.1. Method

Details of the calculations are already presented in our earlier work [24], so we only focus on the essentials. The R-matrix method [27] as implemented in the UKRMol codes [28] starts by dividing the configuration space into two distinct regions [29] by a sphere, here of radius $12 a_{0}$, centred at the centre-of-mass of the $\mathrm{He}_{2}^{+}$molecule. This encloses the wave function of the 3-electron target $\mathrm{He}_{2}^{+}$ ion. In the inner region, the wave functions for the target + scattering electron system $\left(\mathrm{He}_{2}^{+}+\right.$electron $)$is given by:

$$
\begin{align*}
\Psi_{k}^{N+1} & \left(x_{1}, \ldots, x_{N+1}\right) \\
= & \mathcal{A} \sum_{i j} a_{i j k} \phi_{i}^{N}\left(x_{1}, \ldots, x_{N}\right) u_{i j}\left(x_{N+1}\right) \\
& +\sum_{i} b_{i k} \chi_{i}^{N+1}\left(x_{1}, \ldots, x_{N+1}\right) \tag{1}
\end{align*}
$$

Figure 1. Potential energy curves of the lowest singlet ${ }^{1} \Sigma_{g}^{+}\left(n p \sigma(\right.$ green $), n f \sigma$ (magenta) ), ${ }^{1} \Sigma_{u}^{+}(n s \sigma),{ }^{1} \Pi_{g}(n p \pi),{ }^{1} \Pi_{u}(n d \pi)$ and ${ }^{1} \Delta_{u}(n d \delta)$ states of $\mathrm{He}_{2}$. The symmetry of each set of bound states is indicated in the panel. Continuous curves: present calculation. Black dotted and dashed curves in the ${ }^{1} \Sigma_{g}^{+},{ }^{1} \Sigma_{u}^{+}$and ${ }^{1} \Pi_{g}$ figures: Yarkony [21] and Wasilewski et al. [35] respectively. In each panel, the top black thick curve is the ground $\mathrm{X}^{2} \Sigma_{u}^{+}$state of $\mathrm{He}_{2}^{+}$.
where $\mathcal{A}$ is the anti-symmetrisation operator, $u_{i j}$ are known as continuum orbitals, $x_{i}$ are the spatial and spin coordinates of electron $i, \phi_{i}^{N}$ is the wave functions of the $i^{\text {th }}$ target state and $\chi_{i}$ are two-centre $L^{2}$ functions constructed as products of target occupied and virtual molecular orbitals. The variational coefficients $a_{i j k}$ and $b_{i k}$ are determined by diagonalising the Hamiltonian matrix [30]. No allowance is made for relativistic effects such as spin-orbit coupling.

### 2.2. Target calculations

It is known that the basis sets play an important role in the quality of the calculation. For the present work, we use the cc-pVTZ Gaussian basis set for $\mathrm{He}_{2}^{+}$, which include polarisation functions. An initial set of molecular orbitals was obtained by performing self-consistent field (SCF) calculations for the $\mathrm{X}^{2} \Sigma_{u}^{+}$state of $\mathrm{He}_{2}^{+}$, although in practice the choice of orbitals is not important in a full configuration interaction (FCI) calculation. The two lowest $\mathrm{He}_{2}^{+}$states, $\mathrm{X}^{2} \Sigma_{u}^{+}$and $\mathrm{A}^{2} \Sigma_{g}^{+}$, were included in the close-coupling expansion of the trial wave function of the
scattering system; the other target states lie too high in energy to contribute significantly at the energies considered here. Each target state was represented by an FCI wave function. Our FCI calculations performed for the ground state $\mathrm{X}^{2} \Sigma_{u}^{+}$and the first excited state $\mathrm{A}^{2} \Sigma_{g}^{+}$of the $\mathrm{He}_{2}^{+}$molecular ion were in very close agreement with high accuracy calculations [24].

### 2.3. Scattering calculations

The scattering calculations performed in this work were carried out using the fixed-nuclei formulation of R matrix theory.This scattering calculations used a twoterm close-coupling expansion based on the FCI representation of the $\mathrm{He}_{2}^{+} \mathrm{X}^{2} \Sigma_{u}^{+}$and $\mathrm{A}^{2} \Sigma_{g}^{+}$target states. To represent the continuum Gaussian-Type Orbitals (GTOs) were placed at the centre of the R-matrix sphere; the functions involved partial waves up to $\ell=4$ (g functions) and were taken from Faure et al. [31]. The FCI $L^{2}$ functions were generated by allowing all 4 electrons to occupy any target orbital subject only to the constraints of total symmetry. These $L^{2}$ terms relax the orthogonality

Figure 2. Potential energy curves of the lowest triplet ${ }^{3} \Sigma_{g}^{+}(n p \sigma),{ }^{3} \Sigma_{u}^{+}(n s \sigma),{ }^{3} \Pi_{g}(n p \pi),{ }^{3} \Pi_{u}(n d \pi)$ and ${ }^{3} \Delta_{u}(n d \delta)$ states of $\mathrm{He}_{2}$. The symmetry of each set of bound states is indicated in the panel. Continuous curves: present calculation. Black dotted and dashed curves in the ${ }^{3} \Sigma_{g}^{+},{ }^{3} \Sigma_{u}^{+}$and ${ }^{3} \Pi_{g}$ figures; Yarkony [21] and Wasilewski et al. [35]. In each panel, the top black thick curve is the ground X ${ }^{2} \Sigma_{u}^{+}$ state of $\mathrm{He}_{2}^{+}$.
constraint between the continuum and target functions, allow for high $\ell$ behaviour of the scattered electron in the region of the target and for short-range polarisation effects. At long-range (in the outer region) polarisation is at least partially allowed for by the dipole coupling of the two electronic states.

Calculations were performed for singlet and triple spin symmetries and using $C_{2 v}$ point group symmetry. Our results have been recast using standard linear molecule symmetry notation.

### 2.4. Bound states

After solving the inner region problem, the solutions were used to build the R-matrix on the boundary. To use a scattering calculation as the basis for bound state finding requires adaptation of the standard R-matrix method and in particular the calculation of wavefunctions in the outer region. For a bound state, these functions must asymptotically tend to zero and match inner region functions on the R-matrix boundary. We used the algorithm

Figure 3. Effective quantum number of $\mathrm{He}_{2}$ singlet bound states ${ }^{1} \Sigma_{g}^{+}(n p \sigma, n f \sigma),{ }^{1} \Sigma_{u}^{+}(n s \sigma, n d \sigma, n g \sigma),{ }^{1} \Pi_{g}(n p \pi, n f \pi),{ }^{1} \Pi_{u}(n d \pi$, $n g \pi)$ and ${ }^{1} \Delta_{u}(n d \delta)$ as function of the bond length. The I character of each state is indicated by the following symbols: circle : $s$-state, diamond: p -state, square: d -state triangle: $f$-state.
of Sarpal et al. [25] to find such states. The procedure uses an asymptotic expansion due to Gailitis [32] to determine the wavefunction at some intermediate distance, here of $30.1 \mathrm{a}_{0}$. From here the wavefunction was integrated inwards using an improved Runge-Kutta-Nystrom integration procedure, as implemented by Zhang et al. [33]; the bound state searching algorithm uses a nonlinear, quantum defect-based grid [34].

Figure 4. Effective quantum number of $\mathrm{He}_{2}$ singlet bound states ${ }^{3} \Sigma_{g}^{+}(n p \sigma, n f \sigma),{ }^{3} \Sigma_{u}^{+}(n s \sigma, n d \sigma, n g \sigma),{ }^{3} \Pi_{g}(n p \pi, n f \pi),{ }^{3} \Pi_{u}(n d \pi, n g \pi)$ and ${ }^{3} \Delta_{u}(n f \delta)$ as function of the bond length. The $/$ character of each state is indicated by the following symbols:circle $: s$-state, diamond : $p$-state, square : d-state triangle: f-state.
the ion. Vertical excitation energies (the energy difference between the ground and an excited state as taken at the ground state equilibrium bondlength) for some of the lower lying states of $\mathrm{He}_{2}$ are compared with experimental data of Huber and Herzberg [9] and other calculations. Our excitation energies are in good agreement and are within 0.16 eV of the experiments and the other calculations present in the table. We also present in Tables 1-4 our calculated quantum defects for these states for the fixed internuclear separation of $2.00 a_{0}$.

To obtain potential energy curves for Rydberg states of $\mathrm{He}_{2}$ our calculations were repeated for 35 bondlengths in the range $R=1.0$ to 3.5 . Figures 1 and 2 display, respectively, singlet ${ }^{1} \Sigma_{g}^{+},{ }^{1} \Sigma_{u}^{+},{ }^{1} \Pi_{u},{ }^{1} \Pi_{g},{ }^{1} \Delta_{u}$ and triplet ${ }^{3} \Sigma_{g}^{+}$, ${ }^{3} \Sigma_{u}^{+},{ }^{3} \Pi_{g},{ }^{3} \Pi_{u},{ }^{3} \Delta_{u}$ Rydberg states of $\mathrm{He}_{2}$ as a function of bond separation. All curves couple to the ground state of the ion $\mathrm{X}^{2} \Sigma_{u}^{+}$and are more or less parallel to this state, as might be expected for Rydberg states. From Figures 1 and 2, it is seen that our curves are in satisfactory agreement with the multi-configuration selfconsistent field (MCSCF) calculations of Sunil et al. [19]

Table 5. Spectroscopic constants of singlet $\mathrm{A}^{1} \Sigma_{u}^{+}, \mathrm{C}^{1} \Sigma_{g}^{+}, \mathrm{B}^{1} \Pi_{g}$ and $\mathrm{F}^{1} \Pi_{u}$ and triplet a ${ }^{3} \Sigma_{u}^{+}, \mathrm{c}^{3} \Sigma_{g}^{+}, \mathrm{b}^{3} \Pi_{g}$ and $\mathrm{f}^{3} \Pi_{u}$ Rydberg states of $\mathrm{He}_{2}$.

[^3]and CEPA-PNO and PNO-CI calculations of Wasilewski et al. [35] for the range of bond lengths considered in the present calculations. Figures 1 and 2 also compare calculations performed in this work with experimental results of Sprecher et al. [36] for the lowest four $n p \sigma^{3} \Sigma_{g}^{+}$and $n p \sigma^{3} \Pi_{g}$ Rydberg states of $\mathrm{He}_{2}$. These figures show that there are some similarity between our potential curves and those of Sprecher et al. [36] but not complete agreement. The slight differences observed can be accounted for by the difference in approach. A more informative method of considering the Rydberg states as a function of inter-nuclear distance $R$ is to look at quantum defects as a function of $R$. Figures 3 and 4 show our effective quantum number of $\mathrm{He}_{2}$ for singlet and triplet bound states, respectively. It can be seen that the effective quantum numbers show a weak dependence on the internuclear separation. Our methodology in essence is designed to determine quantum defects and can be expected to give approximately constant errors with respect to quantum defects rather than absolute or excitation energies. This means that the accuracy with which the binding energy of higher-lying states is determined in our calculations should improve as $n$ increases.

From our calculated potential energy curves, the analytical potential energy functions of singlet $\mathrm{A}^{1} \Sigma_{g}^{+}, \mathrm{B}^{1} \Pi_{g}$, $\mathrm{C}^{1} \Sigma_{u}^{+}, \mathrm{F}^{1} \Pi_{u}$ and triplet a ${ }^{3} \Sigma_{u}^{+}, \mathrm{b}^{3} \Pi_{g}, \mathrm{c}^{3} \Sigma_{g}^{+}, \mathrm{f}^{3} \Pi_{u}$ Rydberg states of $\mathrm{He}_{2}$ were fitted with Murrell-Sorbie(MS) [37] potential energy functions. The spectroscopic constants of each states are calculated through the relationship between analytical potential energy function and the spectroscopic constants [38]. Calculated spectroscopic constants are listed in Table 5 and compared with experimental results of Focsa et al. [1], Huber and Herzberg [9] and theoretical results obtained by Yarkony [21] and Wasilewski et al. [35]. It can be seen that our calculated $T_{e}$ are very close to the experimental results of Sprecher et al. [36]. The other spectroscopic parameters are generally in agreement with the experiment and other theoretical works but that we can obtain results with the same level of accuracy for all observed states and, indeed, many more.

## 4. Conclusions

We have studied electron collisions with the $\mathrm{He}_{2}^{+}$molecular ion using UK R-Matrix molecular codes. Potential energy curves and quantum defects for singlet and triplet Rydberg states have been calculated as a function of internuclear separation. Our vertical excitation energies at 2.00 are in good agreement with the experiment. Spectroscopic constants of singlet $\mathrm{A}^{1} \Sigma_{g}^{+}, \mathrm{B}^{1} \Pi_{g}, \mathrm{C}^{1} \Sigma_{u}^{+}, \mathrm{F}^{1} \Pi_{u}$ and triplet $\mathrm{a}^{3} \Sigma_{u}^{+}, \mathrm{b}^{3} \Pi_{g}, \mathrm{c}^{3} \Sigma_{g}^{+}, \mathrm{f}^{3} \Pi_{u}$ Rydberg states of
$\mathrm{He}_{2}$ are determined in the present work are in agreement with the experimental data and others theoretical calculations. The data presented in this work and the previous one [24], when combined, provide relevant parameters needed to calculate cross-section of DR and related processes of $\mathrm{He}_{2}$.
