ABSTRACT

Background

Admission avoidance hospital at home provides active treatment by healthcare professionals in the patient's home for a condition that would otherwise require acute hospital inpatient care, and always for a limited time period. This is the fourth update of this review.

Objectives

To determine the effectiveness and cost of managing patients with admission avoidance hospital at home compared with inpatient hospital care.

Search methods

We searched the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, Embase, and CINAHL on 24 February 2022, and checked the reference lists of eligible articles. We sought ongoing and unpublished studies by searching ClinicalTrials.gov and WHO ICTRP, and by contacting providers and researchers involved in the field.

Selection criteria

Randomised controlled trials recruiting participants aged 18 years and over. Studies comparing admission avoidance hospital at home with acute hospital inpatient care.

Data collection and analysis

We followed the standard methodological procedures expected by Cochrane and the Effective Practice and Organisation of Care (EPOC) Group. We performed meta-analysis for trials that compared similar interventions, reported comparable outcomes with sufficient data, and used individual patient data when available. We used the GRADE approach to assess the certainty of the body of evidence for the most important outcomes.

Main results

We included 20 randomised controlled trials with a total of 3100 participants; four trials recruited participants with chronic obstructive pulmonary disease; two trials recruited participants recovering from a stroke; seven trials recruited participants with an acute medical

Admission avoidance hospital at home (Review)

Copyright © 2024 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

condition who were mainly older; and the remaining trials recruited participants with a mix of conditions. We assessed the majority of the included studies as at low risk of selection, detection, and attrition bias, and unclear for selective reporting and performance bias.

For an older population, admission avoidance hospital at home probably makes little or no difference on mortality at six months' follow-up (risk ratio (RR) 0.88, 95% confidence interval (CI) 0.68 to 1.13; $P = 0.30$; $I^2 = 0\%$; 5 trials, 1502 participants; moderate-certainty evidence); little or no difference on the likelihood of being readmitted to hospital after discharge from hospital at home or inpatient care within 3 to 12 months' follow-up (RR 1.14, 95% CI 0.97 to 1.34; $P = 0.11$; $I^2 = 41\%$; 8 trials, 1757 participants; moderate-certainty evidence); and probably reduces the likelihood of living in residential care at six months' follow-up (RR 0.53, 95% CI 0.41 to 0.69; $P < 0.001$; $I^2 = 67\%$; 4 trials, 1271 participants; moderate-certainty evidence).

Hospital at home probably results in little to no difference in patient's self-reported health status (2006 patients; moderate-certainty evidence). Satisfaction with health care received may be improved with admission avoidance hospital at home (1812 participants; low-certainty evidence); few studies reported the effect on caregivers. Hospital at home reduced the initial average hospital length of stay (2036 participants; low-certainty evidence), which ranged from 4.1 to 18.5 days in the hospital group and 1.2 to 5.1 days in the hospital at home group. Hospital at home length of stay ranged from an average of 3 to 20.7 days (hospital at home group only). Admission avoidance hospital at home probably reduces costs to the health service compared with hospital admission (2148 participants; moderate-certainty evidence), though by a range of different amounts and using different methods to cost resource use, and there is some evidence that it decreases overall societal costs to six months' follow-up.

Authors' conclusions

Admission avoidance hospital at home, with the option of transfer to hospital, may provide an effective alternative to inpatient care for a select group of older people who have been referred for hospital admission. The intervention probably makes little or no difference to patient health outcomes; may improve satisfaction; probably reduces the likelihood of relocating to residential care; and probably decreases costs.

PLAIN LANGUAGE SUMMARY

'Hospital at home' services to avoid admission to hospital

What is the aim of this review?

The aim of this Cochrane Review was to find out if providing health care in an admission avoidance hospital at home setting improves patient health outcomes and reduces health service costs.

Key messages

Admission avoidance hospital at home probably makes little or no difference to risk of death; probably increases the chances of living at home at six months' follow-up; and may be slightly less expensive.

What was studied in this review?

There continues to be more demand for acute hospital beds than there are beds available. One way to reduce reliance on hospital beds is to provide people with acute health care at home, sometimes called 'admission avoidance hospital at home'. In contrast, 'early discharge hospital at home' refers to patients being discharged early from hospital to be treated at home; this topic has been reviewed separately.

What did we want to find out?

We wanted to find out if hospital at home makes a difference to patient health outcomes and to living independently at home. We also wanted to find out if it was less expensive than hospital care, and if it affects length of stay in treatment and patient satisfaction.

What did we do?

We searched for studies that compared hospital at home treatment for an acute health event with inpatient hospital care. We compared and summarised the results of the studies, and rated our confidence in the evidence based on factors such as study methods and sizes.

What did we find?

We found 20 studies, of which four were identified for this update, with a total of 3100 patients with a range of acute conditions. Four studies recruited participants with chronic obstructive (lung) disease; two studies recruited participants recovering from a stroke; seven studies recruited participants with a (sudden or short-term) medical condition who were mainly older; and the remaining studies recruited participants with a mix of conditions.

When compared to in-hospital care, admission avoidance hospital at home services for a select group of patients probably make little or no difference to risk of death or to the likelihood of being taken to hospital in the next 3 to 12 months, and probably increase the chances of

Admission avoidance hospital at home (Review)

living at home at six months' follow-up. Patients who receive care at home may have increased satisfaction compared to those in hospital; however, the effects of this type of care on the caregivers who support them are unclear. Hospital at home probably results in little to no difference in patients' health status. Hospital at home decreases the amount of time patients spend in hospital, while length of stay in hospital at home tended to be longer than a typical hospital stay. Admission avoidance hospital at home probably decreases treatment costs, though by a range of different amounts.

What are the limitations of the evidence?

Due to the small size of most of the studies, we are moderately confident that admission avoidance hospital at home does not make a difference to the number of people who died when compared to in-hospital care. Our confidence in the evidence for readmission and living in residential care was reduced to moderate because the lengths of follow-up differed among studies. We are moderately confident in the evidence for patient-reported health status, as participants were aware of which treatment they were getting, which could have influenced the results. We have little confidence in the evidence on patient satisfaction because not many studies reported this outcome, and on length of stay because length of stay varied across studies. We are moderately confident in the evidence for cost because only three trials looked at this fully.

How up-to-date is the review?

We searched for studies published up to February 2022.

SUMMARY OF FINDINGS

Summary of findings 1. Admission avoidance hospital at home compared with inpatient admission for older people requiring admission to hospital

Admission avoidance hospital at home compared with inpatient admission for older people requiring admission to hospital

Patient or population: older people requiring hospital admission

Settings: home

Intervention: admission avoidance hospital at home

Comparison: inpatient care

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	Number of participants (studies)	Certainty of the evidence (GRADE)
	Assumed risk	Corresponding risk			
	Inpatient care	Admission avoidance hospital at home			
Mortality (6 months' follow-up) (using data from trials and published data)	Study population		RR 0.88 (0.68 to 1.13)	1502 (5 studies) ^A	⊕⊕⊕⊕ ^a Moderate
	208 per 1000	183 per 1000 (141 to 235)			
Admission to hospital (3 to 12 months' follow-up) (using individual patient data and published data)	Study population		RR 1.14 (0.97 to 1.34)	1757 (8 studies) ^B	⊕⊕⊕⊕ ^b Moderate
	407 per 1000	464 per 1000 (395 to 546)			
Living in residential care at follow-up (6 months' follow-up)	Study population		RR 0.53 (0.41 to 0.69)	1271 (4 studies) ^C	⊕⊕⊕⊕ ^b Moderate
	124 per 1000	66 per 1000 (51 to 85)			

Patient self-reported health status	Patient-reported health status was largely the same for participants treated in hospital at home and hospital, with some reporting higher quality of life or better health status in hospital at home. ^D	-	2006 (9 studies)	⊕⊕⊕⊕ ^c Moderate
Patient satisfaction	Patients allocated to hospital at home reported higher levels of satisfaction on average; a small proportion preferred hospital, or satisfaction was equal between groups. ^E	-	1812 (8 studies)	⊕⊕⊕⊕ ^d Low
Length of stay in hospital and hospital at home	Hospital at home reduced average length of stay in hospital, which ranged from an average of 4.1 to 18.5 days in the hospital group to 1.2 to 5.1 days in the hospital at home group. ^F Hospital at home length of stay ranged from an average of 3 to 20.7 days (hospital at home group only). ^G Length of stay for the acute episode ranged from a mean increase of 0.7 to 9.1 days ^F for the hospital at home group compared to the hospital group.	-	2036 (11 studies)	⊕⊕⊕⊕ ^e Low
Cost and resource use	Hospital at home was generally less costly than hospital care, with a range of estimates for the mean reduction per episode with different levels of certainty, from USD -215 (P = 0.38) to GBP -1981 (95% CI -2551 to -1411). ^H Estimates for the difference in total health and social care costs for a variety of follow-up durations also varied, ranging from GBP -1015.7 (95% CI -2735.5 to 644.8) to GBP -2265 (95% CI -4279 to -252). ^I	-	2148 (12 studies)	⊕⊕⊕⊕ ^f Moderate

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% CI) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: confidence interval; **RR:** risk ratio

GRADE Working Group grades of evidence

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.

^aWe downgraded the certainty of the evidence by one level to moderate due to imprecision of the estimate.

^bWe downgraded the certainty of the evidence by one level to moderate due to indirect comparisons between studies.

^cWe downgraded the certainty of the evidence by one level to moderate due to risk of performance bias since patients cannot be blinded to the intervention.

^dWe downgraded the certainty of the evidence by two levels to low as only 35% of the studies reported this outcome, and there is a risk of detection bias due to subjective reporting of this outcome.

^eWe downgraded the certainty of the evidence by two levels to low due to imprecision and indirect comparisons between studies.

^fWe downgraded the certainty of the evidence by one level to moderate since only three trials reported a full cost analysis.

BACKGROUND

In the last 20 years, efforts to manage the steady increase in hospital admissions have included expanding out-of-hospital services. Examples include hospital at home services, which are designed to avoid a hospital admission or to provide early supported discharge from hospital (Leong 2021; Oliver 2021). Possible benefits of these services include releasing hospital beds; reducing the risk of adverse events associated with time in hospital (Rafter 2015); loss of independence associated with prolonged hospitalisations (Loyd 2020); receiving rehabilitation within the home environment (Kimmel 2020); and improved patient satisfaction and communication (Leff 2006).

Recent developments in remote monitoring technology, as well as pressures on health systems caused by the COVID-19 pandemic, have motivated more countries to prioritise hospital at home services. Examples include Queensland Australia Hospital in the Home (Mackay 2023; Queensland Government 2022), Spain (Nogues 2021), and the UK, where NHS England has committed to funding the set-up of virtual wards (otherwise known as 'hospital at home'), and Integrated Care Systems have been asked to deliver capacity equivalent to 40 to 50 virtual ward 'beds' per 100,000 population (NHS England 2021). In Scotland, health boards are required to provide hospital at home services, and some of these services have been running for many years (British Geriatrics Society 2022). In Spain, hospital at home units became popular in the 1990s, and gradually progressed to most of the country (de Sousa Vale 2020). In Australia, 'hospital in the home' activity is also growing, accounting for 3.7% of admissions from 2011 to 2017, and there are calls for more systematic monitoring and oversight (Montalto 2020).

The type of patient treated in hospital at home services varies, as does the use of technology, similar to the variation in hospitals. Some services are designed to care for specific conditions, such as chronic obstructive pulmonary disease, or to provide specific skills such as parenteral nutrition (Kumpf 2019). These services usually have close ties with acute hospitals and may be encouraged by the different structure of incentives in insurance-based systems of health care by providing the type of service that is reimbursed.

Description of the condition

The demographic shift of a rising number of older people has increased the demand for hospital-level care. For example, in the UK more than 40% of people admitted to hospital are over 65 years of age (NHS Digital 2019; WHO 2021 to 2030), and between 2006 and 2018 there was a 59% increase in the number of people aged over 85 who required emergency hospital admission (Steventon 2018). Healthcare decision-makers in a number of countries are attempting to reconfigure services to deal with a year-on-year increase in hospital admissions, often with an inadequate evidence base (Nolte 2008; Steventon 2018). These changes have raised concerns that the pressure of delivering health care to greater numbers may be at odds with the provision of person-centred, high-quality care (RCP 2017). In addition to ageing, other factors such as remote monitoring are driving the adoption of hospital at home services.

Description of the intervention

The majority of admission avoidance hospital at home services provide co-ordinated, multidisciplinary health care in the home for people who would otherwise be admitted to hospital (Arsenault-Lapierre 2021; Leff 2009). Similar to hospitals, services are adapted to suit the patient population. People are admitted to admission avoidance hospital at home after assessment in the community by their primary care physician or in the emergency department or a medical admissions unit. Hospital at home may also provide hospital-level care following early discharge from hospital (we have conducted a parallel systematic review of early discharge hospital at home, recently updated with no new studies identified (Gonçalves-Bradley 2017), and a review of home-based end-of-life care (Shepperd 2016b).

In single-payer systems, hospital at home is commonly integrated with existing services, for example using telehealth that is routinely available, or existing emergency services or out-of-hours stand-by services to provide publicly funded 24-hour cover for patients if they deteriorate. This is the case in the UK, Spain, and Canada.

How the intervention might work

As well as reducing the demand for acute hospital beds, receiving hospital at home may lower the risk of functional decline from the limited mobility that can occur during an admission to hospital. This may be particularly beneficial for older people living with frailty, by providing co-ordinated health care in the less restrictive home environment and thereby providing patients with the opportunity for continued involvement in activities of daily living (Covinsky 2003).

Why it is important to do this review

With the current policy emphasis on care closer to home (WHO 2021 to 2030), and concern about the steadily increasing demand for hospital bed-based care (Monitor 2015; Virtual Wards 2022), we are updating this review to incorporate new randomised evidence. Along with more widespread use of admission avoidance hospital at home services, concerns have been raised about standards of care, lack of data, oversight systems, and the role of financial incentives in insurance-based health systems that motivate providers to establish these services (Batt 2023). An up-to-date systematic review of the global evidence is needed to establish whether hospital at home is effective and cost-effective when compared with bed-based hospital care, or if there is a risk that it reduces the quality of care (Batt 2023). This is the fourth update of this review (Shepperd 2016a).

OBJECTIVES

To determine the effectiveness and cost of managing patients with admission avoidance hospital at home compared with inpatient hospital care.

METHODS

Criteria for considering studies for this review

Types of studies

Randomised controlled trials.

Types of participants

This review included evaluations of admission avoidance hospital at home schemes involving people aged 18 years and over. We did not include people with long-term care needs unless they required admission to hospital for an acute episode of care. We excluded evaluations of obstetric, paediatric, and mental health hospital at home schemes from the review as our preliminary literature searches suggested that separate reviews would be justified for each of these groups. For the purposes of this review, we defined older patients as those aged 65 years and older.

Types of interventions

Studies comparing admission avoidance hospital at home with acute hospital inpatient care. The admission avoidance hospital at home studies may have admitted patients directly from the community, thereby avoiding physical contact with the hospital, or may have admitted from the emergency room or an acute assessment unit. We used the following definition to determine whether studies should be included in the review: hospital at home is a service that can avoid the need for hospital admission by providing active treatment by healthcare professionals (including doctors) in the patient's home for a condition that would otherwise require acute hospital inpatient care, and always for a limited time period. In particular, hospital at home has to offer a specific service to patients in their home requiring healthcare professionals to take an active part in the patient's care. If hospital at home were not available, then the patient would be admitted to an acute hospital ward. We have therefore excluded the following services from this review:

- services providing long-term care;
- services provided in outpatient settings or postdischarge from hospital; and
- self-care by the patient in their home such as self-administration of an intravenous infusion.

Types of outcome measures

Primary outcomes

- Mortality.
- Admission to hospital.

Secondary outcomes

- Living in residential care at follow-up.
- Patient self-reported health status: quality of life, functional status, psychological health.
- Satisfaction: patient, caregiver, health professionals.
- Length of stay in hospital and hospital at home.
- Cost and resource use.
- Clinical outcomes.

Search methods for identification of studies

Electronic searches

For this update we searched the following databases on 24 February 2022 for references published since 2 March 2016, the last version of this review:

- Cochrane Central Register of Controlled Trials (CENTRAL; 2022, Issue 2);

- MEDLINE (Ovid) (MEDALL);
- Embase (Ovid);
- CINAHL (Cumulative Index to Nursing and Allied Health Literature) (EBSCOhost).

We sought ongoing and unpublished studies by searching ClinicalTrials.gov and the World Health Organization International Clinical Trials Registry Platform (WHO ICTRP) and by contacting providers and researchers involved in the field.

Search strategies are comprised of natural language and controlled vocabulary terms. Search terms for this update were revised based on terminology used in studies included in previous versions of the review. We applied no limits on language. We ran searches from 2015 onwards, the date of publication of the previous version of the review. In databases where it was possible and appropriate, study design filters for randomised trials were used; in MEDLINE we used a modified version of the Cochrane Highly Sensitive Search Strategy for identifying randomised trials in MEDLINE: sensitivity- and precision-maximising version (2008 revision) (Lefebvre 2021). Limits were used in Embase to remove MEDLINE records in order to avoid duplication in downloaded results. Remaining results were deduplicated in EndNote against each other and against results from searches conducted for previous versions of the review. All search strategies used in this version of the review are provided in Appendix 1. Search strategies and search methods used in previous versions of the review are published within those prior publications.

Searching other resources

We searched the following trial registries on 14 November 2022 (Appendix 1):

- WHO ICTRP (trialsearch.who.int);
- US National Institutes of Health Ongoing Trials Register ClinicalTrials.gov (clinicaltrials.gov).

We checked the reference lists of articles identified electronically for evaluations of hospital at home and obtained potentially relevant articles. We checked relevant systematic reviews for other relevant studies.

Data collection and analysis

For a previous version of this review we contacted the investigators of 10 of the included trials that recruited similar populations, inviting them to contribute individual patient data (IPD) to the hospital at home admission avoidance collaborative review (Shepperd 2005), and had access to IPD for one new study for this update (Shepperd 2021).

Selection of studies

Three review authors (KE, SS, DGB) read all the abstracts in the records retrieved by the electronic searches to identify potentially eligible publications. We retrieved the full-text papers for these publications, and two review authors (KE, SS, SI or DGB) independently assessed their eligibility. We selected studies for the review according to the prespecified inclusion criteria and resolved any disagreements by discussion. As an author of one of the studies (Shepperd 2021), SS was not involved in assessing their own study for inclusion, risk of bias, or data extraction.

Data extraction and management

Four review authors (SS, SI, DGB, KE) independently completed data extraction using a good-practice extraction form developed by Cochrane that was modified and amended for the purposes of this review (EPOC 2015a).

Assessment of risk of bias in included studies

Four review authors (SS, SI, DGB, KE) independently assessed risk of bias in the included studies using the suggested risk of bias criteria for Cochrane Effective Practice and Organisation of Care (EPOC) reviews (EPOC 2015b):

- random sequence generation;
- allocation concealment;
- baseline outcome measurement;
- baseline characteristics;
- blinding of participants and personnel;
- blinding of outcome assessment;
- incomplete outcome data;
- selective reporting of outcomes.

Measures of treatment effect

We used IPD data and published data to conduct meta-analyses on the outcomes of mortality, admission to hospital after discharge from hospital at home or inpatient care, and place of residence (living in residential care). We used a two-stage approach: first we obtained or calculated the study treatment effects and their standard errors, and then subsequently combined them.

For mortality at three months, treatment effects adjusted for age and sex were estimated in a previous version of the review, based on IPD received from three trialists (Davies 2000; Harris 2005; Wilson 1999). These risk ratios were then combined using fixed-effect inverse variance meta-analysis (Deeks 2001). The pooled effect is expressed as the risk ratio for hospital at home compared with usual hospital care, with 95% confidence interval.

For mortality at six months, we extracted numbers of dead and alive in each group from published data from three studies, Caplan 1999; Ricauda 2008; Tibaldi 2009, and from IPD from two studies (Shepperd 2021; Wilson 1999), and combined this information as unadjusted risk ratios using a fixed-effect model with inverse variance weights. Though studies published some adjusted risk ratios, they varied in the covariates they adjusted for, and therefore it was most straightforward to use only unadjusted estimates.

We analysed the effect of admission avoidance hospital at home on admission to hospital after discharge from hospital at home or inpatient care using IPD received from five trialists (Davies 2000; Harris 2005; Mendoza 2009; Shepperd 2021; Wilson 1999), and published data from three studies (Caplan 1999; Ricauda 2008; Tibaldi 2009), again combined using a fixed-effect model and inverse variance weights. This outcome describes subsequent admission to inpatient hospital care after discharge (from either hospital at home or hospital) for a range of follow-up times (3 to 12 months). We also extracted and presented data for transfer to hospital during the hospital at home episode, but as this only applies to the intervention group, we did not meta-analyse these data.

There were insufficient IPD for living in residential care, therefore for this outcome we used available published data from three studies, Ricauda 2008; Tibaldi 2004; Tibaldi 2009, combined with the unadjusted risk ratio obtained from (Shepperd 2021), using a fixed-effect model with inverse variance weights. The analyses in this review were carried out in Stata 16.1.

Our statistical analyses sought to include all randomised participants, using the intention-to-treat principle. We relied on published data when the IPD did not include the relevant outcomes.

Unit of analysis issues

The unit of allocation was the participant in all trials.

Dealing with missing data

In one data set contributing to the IPD meta-analysis (Davies 2000), some dates were missing for known events, and so we gave the missing event a time at the midpoint between randomisation and last follow-up, or as the midpoint between follow-up times if these were known. For one trial where follow-up was 90 days, we set the time to event as 45 days for three cases in the admission avoidance hospital at home arm and for one case in the control group where we knew death had occurred but we did not have a date (Davies 2000).

Assessment of heterogeneity

We quantified heterogeneity by Cochran's Q and the I² statistic (Cochran 1954), the latter quantifying the percentage of the total variation across studies that is due to heterogeneity rather than chance (Higgins 2003); smaller percentages suggest less observed heterogeneity.

Assessment of reporting biases

If we identified an adequate number of studies (more than 10) and included these in a meta-analysis, we explored publication bias using a funnel plot to visually assess funnel plot asymmetry (Higgins 2019).

Data synthesis

We used IPD when this information was available for studies that recruited similar populations (Davies 2000; Harris 2005; Mendoza 2009; Shepperd 2021; Wilson 1999). The pooled effect is expressed as the risk ratio for hospital at home compared with usual hospital care. Throughout the analyses, we took statistical significance at the two-sided 5% level ($P < 0.05$), presenting data as the estimated effect with 95% confidence intervals. For this update, we conducted the analysis using Review Manager 5 (Review Manager 2020).

When combining outcome data was not possible because of differences in the measurement or reporting of outcomes, or in the case of outcomes that only applied to the intervention group, we presented data from individual studies in tables. Although planned, we did not attempt a direct comparison of costs because the trials collected data on different resources and used different methods to calculate costs.

Subgroup analysis and investigation of heterogeneity

We grouped studies by study population to reduce the amount of variation in the analysis.

Admission avoidance hospital at home (Review)

Sensitivity analysis

We did not conduct a sensitivity analysis.

Summary of findings and assessment of the certainty of the evidence

We assessed our confidence in the evidence by creating a summary of findings table using the approach recommended by the GRADE Working Group, in [Guyatt 2008](#), and specific guidance developed by EPOC ([EPOC 2017](#)), employing GRADEpro GDT software ([GRADEpro GDT 2022](#)). We included the main outcomes of mortality and admission to hospital, as well as living in residential care at follow-up, patient satisfaction, length of stay, patient self-reported health status, and cost and resource use. We used the five GRADE considerations (study limitations, consistency of effect, imprecision, indirectness, and risk of bias) to assess the certainty of the evidence as it relates to the main outcomes ([Guyatt 2008](#)). We used the methods and recommendations described in Chapter 14 of the *Cochrane Handbook for Systematic Reviews of Interventions* ([Higgins 2019](#)).

RESULTS

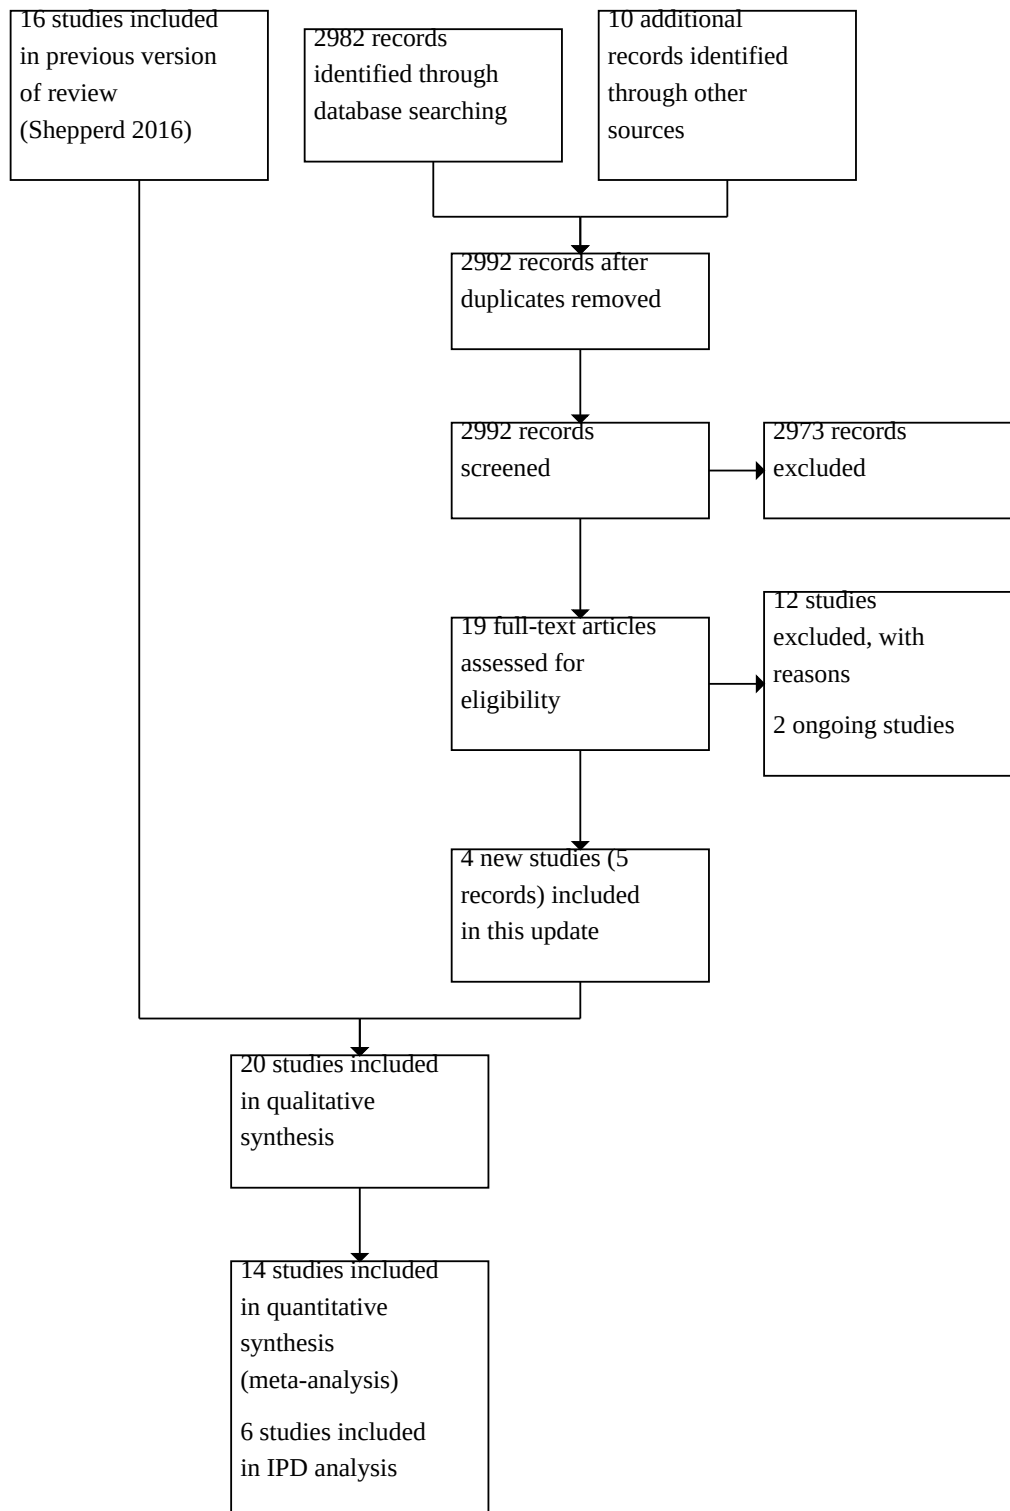

Description of studies

We identified 20 trials that randomised individual participants (N = 3100), of which four were located in this update ([Echevarria 2018](#); [Levine 2018](#) (a pilot study); [Levine 2020](#); [Shepperd 2021](#)) ([Characteristics of included studies](#)).

Results of the search

The updated search retrieved 2982 records from the electronic databases. We found 10 additional records from other sources, for a total of 2992 records after duplicates were removed, of which 2973 were ineligible. We obtained the full texts for the remaining 19 records, four of which fulfilled the inclusion criteria (four trials, five records), bringing the total number of trials included in the review to 20 ([Figure 1](#)). We excluded 12 studies with reasons provided ([Excluded studies](#)). We also identified two ongoing trials ([NCT03156686](#); [Pouw 2018](#); see [Characteristics of ongoing studies](#)).

Figure 1. PRISMA flow diagram.

Included studies

See [Characteristics of included studies](#).

For a previous version of this review, we contacted the investigators of 10 of the included trials that recruited similar populations, inviting them to contribute IPD to the hospital at home admission avoidance collaborative review (Shepperd 2005). We used summaries of this information from the previous review for the three-month mortality comparison using three studies (Davies 2000; Harris 2005; Wilson 1999), and had access to IPD for one new study (Shepperd 2021). We have summarised each study in [Table 1](#), including details of the intervention and population in each study.

Study populations

Four trials recruited participants with chronic obstructive pulmonary disease (COPD), with an average age range of 69.9 to 81 years (Davies 2000; Echevarria 2018; Nicholson 2001; Ricauda 2008). Two trials recruited participants recovering from a moderately severe stroke who were clinically stable, with an average age range of 77.5 to 81 years (Kalra 2000; Ricauda 2004). Seven trials recruited participants with an acute medical condition who were mainly elderly, with an average age range of 76 to 84 years (Andrei 2011; Caplan 1999; Harris 2005; Mendoza 2009; Shepperd 2021; Tibaldi 2009; Wilson 1999). Harris 2005 included two treatment groups and a control (hospital) group. One treatment group was an "admission prevention" group, and the other was an "early discharge" group. Harris provided IPD data for the admission prevention and control groups only. Two trials, one of which was the pilot for the main effectiveness trial, recruited adults attending the emergency department with a primary diagnosis of any infection, heart failure exacerbation, COPD exacerbation, or asthma exacerbation, with an average age of each 62.5 and 65 years respectively (Levine 2018; Levine 2020). There was one trial each for participants with cellulitis, average age 51.5 years (Corwin 2005), community-acquired pneumonia, average age 50 (Richards 2005), fever and neutropenia, average age 47 (Talcott 2011), frail elderly participants with dementia, average age 83.5 (Tibaldi 2004), and neuromuscular disease, average age 45.7 years (Vianello 2013). The 20 trials were conducted in seven countries: Australia (two trials), Italy (five trials), New Zealand (three trials), Romania (one trial), Spain (one trial), the UK (five trials), and the USA (three trials).

Interventions

Details of the intervention components are described in [Table 1](#) and [Table 2](#). Participants were admitted to hospital at home from the emergency room (Andrei 2011; Caplan 1999; Corwin 2005; Davies 2000; Levine 2018; Levine 2020; Mendoza 2009; Nicholson 2001; Ricauda 2004; Ricauda 2008; Richards 2005; Tibaldi 2004; Tibaldi 2009; Vianello 2013), after a hospital assessment (within 24 hours) (Echevarria 2018), the community following referral by

their primary care physician (Harris 2005; Kalra 2000; Wilson 1999), an outpatient department (Talcott 2011), and a hospital acute assessment unit or primary care (Shepperd 2021). For participants allocated to hospital at home, health care was provided by a hospital outreach team (Caplan 1999; Echevarria 2018; Harris 2005; Mendoza 2009; Ricauda 2004; Ricauda 2008; Talcott 2011; Tibaldi 2004; Tibaldi 2009), a mix of outreach and community staff (Davies 2000; Kalra 2000; Levine 2018; Levine 2020; Nicholson 2001; Shepperd 2021; Vianello 2013), or by the general practitioner (GP) and community nursing staff (Corwin 2005; Richards 2005; Wilson 1999). For one trial it was not clear who provided care (Andrei 2011). In two trials, the intervention was provided by Pegasus Health, an independent association of GPs (Corwin 2005; Richards 2005). One trial was a three-group comparison of stroke unit care, inpatient stroke team, and hospital at home (Kalra 2000); we selected the inpatient stroke team as the comparison group, as this was most similar to the comparator in the other trials.

Physiotherapy care was described in 10 of the interventions (Harris 2005; Kalra 2000; Levine 2018; Levine 2020; Nicholson 2001; Ricauda 2004; Ricauda 2008; Shepperd 2021; Tibaldi 2004; Wilson 1999), and occupational therapist care in seven (Harris 2005; Kalra 2000; Levine 2018; Levine 2020; Nicholson 2001; Shepperd 2021; Wilson 1999). A social worker was part of the hospital at home team in 10 of the interventions (Davies 2000; Harris 2005; Kalra 2000; Levine 2018; Levine 2020; Ricauda 2004; Shepperd 2021; Talcott 2011; Tibaldi 2004; Wilson 1999), and a counsellor in one (Talcott 2011). Access to a speech therapist was described in three of the interventions (Kalra 2000; Ricauda 2004; Wilson 1999). In two trials, participants could access a home health aide and medical meals, if required (Levine 2018; Levine 2020). One trial described access to a cultural link worker (Wilson 1999). The intervention in one trial included the use of a portable ventilator; a respiratory therapist made daily visits for the first three days of home care, and district nurses and caregivers were trained in the application of the device and on assisting with coughing (Vianello 2013). District nurses visited daily until recovery from the respiratory tract infection; participants also had telephone access to pulmonary specialists (Vianello 2013).

Excluded studies

The main reason for exclusion was that the trial tested the feasibility of introducing technologies for ameliorating a condition at home (four trials), Duiverman 2019; Hazenberg 2014; Mascardi 2016; NCT02363413, and not hospital at home (see [Characteristics of excluded studies](#)).

Risk of bias in included studies

See [Characteristics of included studies](#). Summaries of the risk of bias assessments for the included studies are presented in [Figure 2](#) and [Figure 3](#).

Figure 2. Risk of bias graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

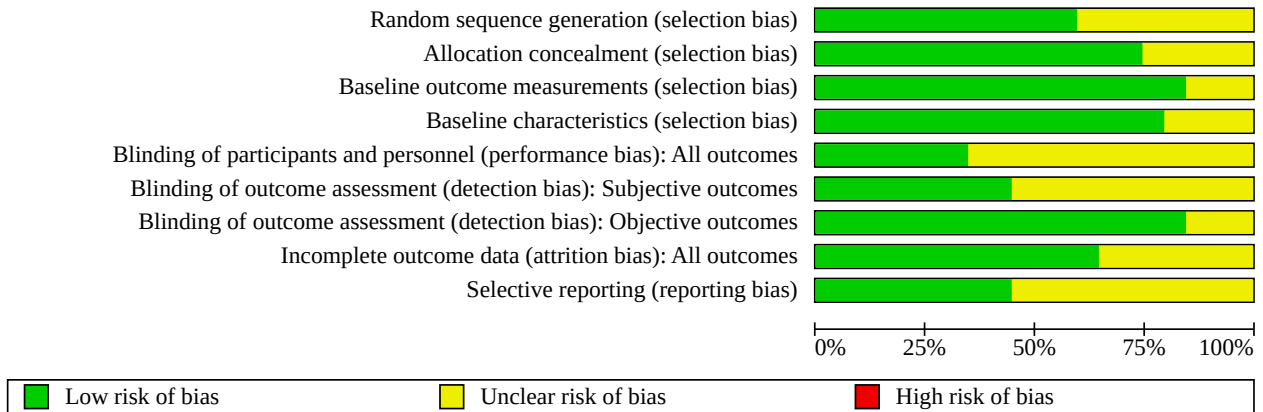

Figure 3. Risk of bias summary: review authors' judgements about each risk of bias item for each included study.

Allocation

In 15 studies concealment of allocation was adequate (Figure 2; Figure 3) (Caplan 1999; Corwin 2005; Davies 2000; Echevarria 2018; Harris 2005; Kalra 2000; Levine 2018; Levine 2020; Mendoza 2009; Ricauda 2008; Richards 2005; Shepperd 2021; Talcott 2011; Tibaldi 2009; Wilson 1999), and in 12 studies sequence generation was adequately described (Caplan 1999; Echevarria 2018; Harris 2005; Kalra 2000; Levine 2018; Levine 2020; Mendoza 2009; Ricauda 2004; Ricauda 2008; Richards 2005; Shepperd 2021; Talcott 2011).

Blinding

We assessed seven studies as having a low risk of performance bias (Davies 2000; Echevarria 2018; Harris 2005; Kalra 2000; Ricauda 2008; Shepperd 2021; Wilson 1999). Three studies were at unclear risk of bias for the measurement of objective outcomes, and nine studies were at low risk of bias for the measurement of subjective outcomes (Figure 3).

Incomplete outcome data

Most studies had a low risk of attrition bias, with seven studies having an unclear risk (Andrei 2011; Mendoza 2009; Nicholson 2001; Ricauda 2004; Richards 2005; Tibaldi 2004; Tibaldi 2009).

Selective reporting

Nine studies were at low risk of bias for selective reporting (Davies 2000; Echevarria 2018; Harris 2005; Kalra 2000; Levine 2020; Ricauda 2008; Shepperd 2021; Tibaldi 2009; Wilson 1999).

Other potential sources of bias

Other sources of bias were not assessed.

Effects of interventions

See: [Summary of findings 1 Admission avoidance hospital at home compared with inpatient admission for older people requiring admission to hospital](#)

See [Summary of findings 1](#) for the main comparison admission avoidance hospital at home versus inpatient admission for older people requiring admission to hospital.

Mortality

We combined IPD for a subset of three studies (N = 420), adjusted for age and sex, for mortality at three months' follow-up (risk ratio (RR) 0.89, 95% confidence interval (CI) 0.55 to 1.45; P = 0.64; N = 420 participants; moderate-certainty evidence) (Davies 2000; Harris 2005; Wilson 1999) (Analysis 1.1). We combined published data from three studies, Caplan 1999; Ricauda 2008; Tibaldi 2009, with data received from trialists of two studies, Shepperd 2021; Wilson 1999, for mortality at six months (RR 0.88, 95% CI 0.68 to 1.13; P =

0.30; N = 1502 participants; moderate-certainty evidence) (Analysis 1.2). Results indicated that admission avoidance hospital at home probably makes little to no difference to mortality when compared with in-hospital care.

Admission to hospital

We analysed the effect of admission avoidance hospital at home on hospital admission after discharge from hospital at home or inpatient care at 3 to 12 months' follow-up using data received from five trialists, Davies 2000; Harris 2005; Mendoza 2009; Shepperd 2021; Wilson 1999, and published data from three studies, Caplan 1999; Ricauda 2008; Tibaldi 2009. Results indicated that admission avoidance hospital at home probably makes little to no difference to hospital admission (RR 1.14, 95% CI 0.97 to 1.34; P = 0.11; I² = 41%; N = 1757 participants; moderate-certainty evidence) (Analysis 1.3). Four trials reported transfer to hospital while receiving hospital at home (Analysis 1.4) (Corwin 2005; Ricauda 2008; Richards 2005; Talcott 2011).

Living in residential care at follow-up

Admission avoidance probably reduces the likelihood of living in residential care, measured at discharge to six months' follow-up (RR 0.53, 95% CI 0.41 to 0.69; P < 0.001; I² = 67%; 4 trials; N = 1271 participants; moderate-certainty evidence) (Analysis 1.5) (Ricauda 2008; Shepperd 2021; Tibaldi 2004; Tibaldi 2009).

Patient self-reported health status

Quality of life

Nine trials assessed health status or quality of life using different measures, as described below (Analysis 1.6).

One trial that recruited people with cellulitis reported 36-Item Short Form Health Survey (SF-36) scores at six days' follow-up. The difference in score from day 0 was compared between the treatment groups; each item is scored between 0 and 100, with a higher score indicating better health; a difference above 0 favours the treatment group (physical component scale mean difference (MD) -5.2, 95% CI -13.7 to 3.2; role physical scale MD 2.2, 95% CI -10.7 to 15.1; pain scale MD -3.8, 95% CI -10.6 to 3.0) (Corwin 2005).

A second trial measuring health status with the SF-36 reported follow-up data at one year for the physical component scale (treatment group (T): 3.6 (-0.5 to 7.7), control group (C): 2.2 (-1.9 to 6.4); P = 0.47) and the mental component scale (T: 4.0 (-0.9 to 8.9), C: 2.8 (-2.4 to 8.0); P = 0.38) (Mendoza 2009). One trial measured quality of life with the SF-12 at six weeks' follow-up and reported similar scores for each group on the physical component (T: 42.2, C: 45.8; P = 0.18) and mental component scale (T: 50.4, C: 51.0; P = 0.81) (Richards 2005).

Admission avoidance hospital at home (Review)

Two trials assessed quality of life using the Nottingham Health Profile at six months' follow-up. Yes/no answers are given for 38 items, which are then weighted to give a score between 0 and 100, with a higher score indicating better health. In these two trials, the change from baseline to six months was compared between treatment groups (T: +1.09 (standard deviation (SD) 2.57) N = 48, C: +0.18 (SD 1.94); P = 0.046) (Tibaldi 2009) and (T: 3.6 (SD 7.9), C: 0.8 (SD 4.5); P = 0.04) (Ricauda 2008).

One trial assessed change from baseline in quality of life when a participant had a health event using the EORTC QLQ-C30, measuring the change before and after the episode (range 0 to 100, higher is better quality of life) (T: 0.58, C: 0.78, P = 0.05; emotional function hospital at home 3.27, hospital -6.94; P = 0.04) (Talcott 2011). One trial reported median values at three months' follow-up for the Sickness Impact Profile (range 0 to 100, higher score is better health) (T: 24 (interquartile range (IQR) 20 to 31), C: 26 (IQR 20 to 31); MD -2, 95% CI -4 to 4; P = 0.73) and the EuroQol (utility score anchored at 0 for death and 1 for perfect health) (T: 0.64, n = 73, C: 0.63, n = 96; MD 0.01, 95% CI -0.12 to 0.09; P = 0.94) (Wilson 1999). Two trials reported mean changes for the EQ-5D: Echevarria 2018 reported small changes from baseline to 14- and 90-day follow-up, and Shepperd 2021 reported that there was likely little or no difference between groups at six months' follow-up.

Functional status

Ten trials reported measures of functional ability, for which higher scores indicate greater independence (see Analysis 1.7 for specific details on the scales used), described as follows.

Caplan 1999 reported scores for instrumental activities of daily living between admission and discharge (MD -0.23, P = 0.04) and the Barthel Index (high score = greater independence) (hospital at home (T): 0.37 (0.27), hospital (C): -0.04 (0.27)). A trial that recruited participants with dementia reported that fewer participants in the hospital at home group had problems with sleep (difference 34%, P < 0.001), agitation and aggression (difference 32.5%, P < 0.001), and feeding (difference 31%, P < 0.001) (Tibaldi 2004).

One trial recruiting participants who had had a stroke reported the number of participants with a favourable outcome measured by the Barthel Index (score of 15 to 20) at three months (T: 106/145 (73%), C: 106/151 (70%); RR 0.96, 95% CI 0.83 to 1.11; P = 0.58) (Kalra 2000). Ricauda 2004, which also recruited participants with a stroke, reported activities of daily living (scale 0 to 6) at six months (median (IQR), T: 4 (2 to 5), C: 4 (2 to 6); P = 0.57). Two trials recruiting participants with COPD reported follow-up data: Ricauda 2008 reported change in activities of daily living at six months (score 0 to 6) (T: 0.12 (SD) 0.64, C: 0.08 (SD 0.73); P = 0.81), and Davies 2000 reported forced expiratory volume in 1 second (FEV1) at three months' follow-up (T: 41.5%, 95% CI 8.2% to 74.8%; C: 41.9%, 95% CI 6.2% to 77.6%).

Two studies recruiting participants with heart failure reported little or no change in activities of daily living measured by the Barthel Index at baseline and six months' follow-up (mean T: -1.95 (SD 9.61), C: -0.30 (SD 10.12)) (Tibaldi 2009); and at one year (T: 4.0, 95% CI -0.9 to 8.9; C: 4.7, 95% CI -2.2 to 11.5; P = 0.21), adjusted for baseline differences (Mendoza 2009). Wilson 1999, which recruited older people with a mix of conditions, assessed functional ability at three months using the Barthel Index (median (IQR) T: 16 (13 to 19), C: 16 (12 to 20)). Levine 2020 reported that patients who

received their health care at home were less sedentary than those in hospital, and that reductions in functional status at 30 days after discharge were similar in both groups. Shepperd 2021 reported little or no difference between groups in activities of daily living measured by the Barthel Index at six months' follow-up (Analysis 1.7).

Psychological health

Seven trials measured cognitive function and depression, detailed as follows (Analysis 1.8).

One trial that recruited participants recovering from a stroke reported that hospital at home may lead to lower scores on the Geriatric Depression Scale (GDS) (lower scores = fewer symptoms) (MD 7 points on a 0-to-30-point scale, P < 0.001) (Ricauda 2004), and one trial reported a lower score at six months for participants who had COPD and were allocated to hospital at home (T: -3.1 (SD 4.7), C: 0.7 (SD 3.2); P < 0.001) (Ricauda 2008). One trial that recruited participants with acute chronic heart failure reported fewer depressive symptoms at six months follow-up (measured by the GDS) for those allocated to admission avoidance hospital at home (mean change T: 1.48 (SD 1.86), C: 0.12 (SD 3.36); P = 0.02) (Tibaldi 2009). Wilson 1999 reported median (IQR) scores for the Philadelphia Geriatric Morale Scale at three months, finding little to no difference between groups (T: 37 (30 to 42), C: 37 (31 to 43); MD 0, 95% CI -4.1 to 4.1). Echevarria 2018 and Shepperd 2021, using the Hospital Anxiety and Depression Scale and the Montreal Cognitive Assessment (MoCA) questionnaire, respectively, reported little or no differences between groups.

Two trials used the Mini-Mental State Examination (max score 30) to assess cognitive functioning at six months' follow-up and reported little to no difference between groups (T: -0.4 (SD 4.0), C: -0.5 (SD 1.8); P = 0.88) (Ricauda 2004); and (T: 0.07 (SD 1.38), C: 0.08 (SD 1.36); P = 0.97) (Tibaldi 2009). One trial that recruited participants with a mix of conditions reported cognitive function scores: mean T: 0.43 (standard error of the mean (SEM) 0.12), C: 0.27 (SEM 0.12); and that fewer people receiving hospital at home care experienced short-term confusion during an episode of care (MD -20.4%, 95% CI -32% to -9%) (Caplan 1999). One trial used the Confusion Assessment Method (CAM) to screen for delirium at baseline, three days, five days, and one month, and reported a difference at one month (T: 10/602 (1.7%), C: 13/297 (4.4%), RR 0.38 (0.19, 0.76); P = 0.006) (Shepperd 2021).

Satisfaction: patient, caregiver, and health professionals

Admission avoidance may increase patient satisfaction with the health care received. Participants allocated to hospital at home care reported higher levels of patient satisfaction across a range of different conditions (8 studies; 1812 participants; low-certainty evidence). Twenty-seven per cent (P < 0.001) more participants with cellulitis in the hospital at home group reported increased satisfaction with their location of care compared with those admitted to hospital (Corwin 2005), and 40% (P < 0.001) more participants with community-acquired pneumonia allocated to hospital at home reported that they were happy with their care (Richards 2005). Two trials (recruiting mainly older participants with a mix of medical conditions) also reported increased levels of satisfaction for those allocated to hospital at home care (median difference of 3 on a 0-to-18-point scale, P < 0.001 (Wilson 1999); and MD of 0.9 on a 4-point scale, P < 0.001 (Caplan 1999)). However, in the latter trial, there was a low response rate for the control group:

Admission avoidance hospital at home (Review)

40% compared with 78% in the hospital at home group (Caplan 1999).

Some participants (6/101; 6%) refused hospital at home care and were admitted to hospital, and a greater number of participants allocated to hospital care (23/97; 24%) were not admitted because of refusal by the participant, caregiver, or general practitioner (Wilson 1999). One trial recruiting participants with COPD reported the number of participants assessing satisfaction with care as very good or excellent (hospital at home 49/52 (94%), hospital 46/52 (88%); $P = 0.83$) (Analysis 1.9) (Ricauda 2008), and one trial reported that overall satisfaction scores favoured hospital at home (Shepperd 2021). Two trials (one pilot study, Levine 2018) found that patients in both groups had the same or similar median global satisfaction score, both indicating high satisfaction, though one point lower in the hospital group in Levine 2020.

One trial reported that caregivers in the hospital at home group had significantly higher levels of satisfaction compared with those in the hospital group (difference -0.8 on a 4-point scale, $P < 0.001$) (Caplan 1999), although the response rate was 27% in the hospital group and 55% in the hospital at home group. A second trial assessed caregiver satisfaction through semi-structured interviews; caregivers reported that although hospital would potentially relieve them from caring, the upheaval of visiting hospital and the accompanying anxiety was a less satisfactory option (Wilson 1999). One trial recruiting participants with COPD reported change in relatives' stress at six months (mean scores (SD) T: 4.6 (5.6), C: 2.6 (6.1); $P = 0.16$) (Analysis 1.10) (Ricauda 2008).

Health professionals' views

One trial evaluated general practitioners' satisfaction with the service (T: 1.17, C: 1.8, score of 1 to 4, high score = excellent, low score = poor); the response rate was poor: 63% in the hospital at home group and 37% in the control group (Analysis 1.11) (Caplan 1999).

Length of stay in hospital and hospital at home

Eleven trials reported the effect of admission avoidance hospital at home on length of hospital stay or hospital at home stay, or both, with differing results (Analysis 1.12). Four trials reported length of stay in hospital, for both the intervention and control groups (Davies 2000; Echevarria 2018; Shepperd 2021; Wilson 1999). Hospital length of stay ranged from an average of 4.1 days, Echevarria 2018, to 18.5 days, Wilson 1999, in the hospital group, and 1.2 days, Echevarria 2018, to 5.1 days, Wilson 1999, in the hospital at home group. Hospital at home length of stay ranged from an average of 3 to 20.7 days (hospital at home group only) (Harris 2005; Levine 2018; Levine 2020; Mendoza 2009; Ricauda 2008; Tibaldi 2009; Wilson 1999). One trial (Singh 2022 for Shepperd 2021) reported a reduction in hospital length of stay of just over a day at six months follow-up for those allocated to hospital at home.

For the total length of stay in the acute episode, admission avoidance hospital at home increased the length of stay or made no difference. The increase ranged from 0.7 days, in Levine 2020, to 9.1 days, in Tibaldi 2009. In one study there was no difference in length of stay between treatment groups (Levine 2018).

Cost and resource use

Three trials reported a full evaluation of healthcare resources and costs (Echevarria 2018; Shepperd 2021; Wilson 1999); one of these trials included informal-care costs (Shepperd 2021). Four trials reported the difference in mean cost per initial acute health episode (Caplan 1999; Nicholson 2001; Shepperd 2021; Wilson 1999); three trials reported the mean cost per patient (Ricauda 2004; Ricauda 2008; Richards 2005); and two trials reported the percentage reduction in median cost of episode and subsequent 30 days (Levine 2018; Levine 2020) (Analysis 1.13).

Admission avoidance hospital at home probably decreases healthcare costs (2148 participants, moderate-certainty evidence) (Caplan 1999; Corwin 2005; Echevarria 2018; Levine 2018; Levine 2020; Mendoza 2009; Nicholson 2001; Ricauda 2004; Ricauda 2008; Richards 2005; Shepperd 2021; Wilson 1999), though by a range of different amounts, and there is some evidence that it decreases overall societal costs to six months' follow-up (Shepperd 2021).

Older participants with a medical condition

One trial reported a cost minimisation analysis (Wilson 1999), finding an initial increase in the mean cost per day for hospital at home (difference GBP 99.71, $P < 0.001$) for all those randomised, and little or no difference in cost at three months' follow-up (GBP -210.9 , 95% CI GBP -1025 to GBP 635.47). When participants refusing their allocated place of care (T: 6/101, C: 23/97) were removed from the analysis, there was a reduction in costs for those receiving hospital at home for the initial episode of care (difference GBP -1070.53 , 95% CI GBP -1843.2 to GBP -245.73) and at three months' follow-up (difference GBP -1063.45 , 95% CI GBP -2043 to GBP -162.7). The difference in mean cost per day between hospital at home and hospital care was reduced, although hospital at home care remained more costly per day (GBP 206.68 versus GBP 133.7, MD GBP 72.98, $P < 0.001$).

Another trial, recruiting mainly older participants with a mix of conditions, examined health service costs using average costs (Board 2000 secondary publication to Caplan 1999), and reported reduced health service costs for the intervention group (T: AUD 1764 (SD AUD 1253), C: AUD 3775 (SD AUD 2496) for an episode of care, MD per episode AUD -2011) and cost per day (T: AUD 191 (SD AUD 58), C: AUD 484 (SD AUD 67.23); MD AUD 293). The costs of the nurse co-ordinator and hospital doctor involved were excluded from this analysis (see Analysis 1.13.1). Mendoza 2009 reported the mean (SD) cost at one-year follow-up (T: EUR 2541 (1334), C: EUR 4502 (2153); difference EUR 1961, $P < 0.001$).

Singh 2022 for Shepperd 2021 compared total health and social care costs, and total societal costs (includes the productivity loss of informal carers costed by the hour). They reported reduced health and social care costs for the intervention group from baseline to six months' follow-up (T: GBP 15,124, C: GBP 17,390; difference GBP -2265 , 95% CI GBP -4279 to GBP -252), adjusting for gender, cognitive decline, utilities, pre-randomisation costs, and site. Total adjusted societal costs were also reduced for the intervention group at six months' follow-up (T: GBP 19,067, C: GBP 21,907; difference GBP -2840 , 95% CI GBP -5495 to GBP -185).

Participants recovering from a stroke

A trial recruiting participants recovering from a stroke compared stroke unit care, inpatient stroke team care, and hospital at home.

Admission avoidance hospital at home (Review)

Regarding immediate care, hospital at home care was less costly than inpatient stroke team care (MD GBP -2096, 95% CI GBP -3272 to GBP -920). The inclusion of costs of informal care, based on the minimum wage, resulted in an MD of GBP -2216 (95% CI GBP -4771 to GBP 339) (Analysis 1.13) (Patel 2004 for Kalra 2000). In another trial recruiting participants with a stroke, a small reduction in mean cost per patient was reported for those allocated to hospital at home (USD 6413.5 versus USD 6504.8) (Ricauda 2004), which translated to a lower cost per day for hospital at home of USD 112.00 (USD 163.0, SD 20.5 versus USD 275.6, SD 27.7; $P < 0.001$).

COPD and community-acquired pneumonia

One trial recruiting participants with COPD reported a lower mean health service cost for participants allocated to hospital at home; hospital costs were based on an average DRG (a diagnostic-related group categorised by resource use) cost per bed day (cost per episode MD GBP -1798, $P < 0.01$) (Nicholson 2001). Another trial recruiting participants with community-acquired pneumonia, again using DRG costs for the control and actual resource use for costing the intervention, reported a reduced cost for those allocated to hospital at home (mean cost per patient T: NZD 1157.9, C: NZD 1556.28) (Richards 2005). Ricauda 2008 reported the total mean cost per patient (T: USD 1175.9, C: USD 1390.9, $P = 0.38$) and the total mean cost per day (T: USD 101.4 (SD 61.3), C: USD 151.7 (SD 96.4)).

Use of other health services and informal care

Davies 2000 reported an increase in referrals for social support for participants with COPD who were allocated to hospital at home. This occurred during the time they were receiving hospital at home or when the control group had been discharged from hospital (24% versus 6%, difference 18%, 95% CI 7.3% to 28.6%) (Analysis 1.13). One trial recruiting participants recovering from a stroke reported that 71% (100/140) of those allocated to hospital at home received informal care, compared with 67% (98/147) receiving care from the inpatient stroke team (Patel 2004). This translated into 979 hours (SD 1749) versus 846 hours (SD 1549) of care over a 12-month period (Analysis 1.13). Singh 2022 for Shepperd 2021 found no significant difference in the total hours of informal care between the treatment groups up to six months' follow-up (mean (SD) T: 594.89 (1093.63), C: 657.64 (1170.87); difference -62.76, 95% CI -224.61 to 99.09).

Clinical outcomes

One trial measured clinical complications, with fewer participants allocated to hospital at home reporting bowel complications (difference -22.5%, 95% CI -34% to -10.8%) or urinary complications (difference -14.4%, 95% CI -25.4% to -3.3%) (Caplan 1999). In a trial recruiting participants with dementia, fewer participants in the hospital at home group were prescribed antipsychotic drugs at discharge (difference -14%, 95% CI -28% to 0.3%) (Tibaldi 2004). One trial that recruited people with cellulitis reported risk of advancement of cellulitis (hazard ratio 0.98, 95% CI 0.73 to 1.32) (Corwin 2005), and one trial recruiting participants with COPD reported that more participants allocated to hospital at home were prescribed an antibiotic (difference 18%, 95% CI 1.4% to 34.6%) (Davies 2000). Talcott 2011 reported the difference in major complications during the episode of care (difference 1%, 95% CI -10% to 13%) (Analysis 1.14).

DISCUSSION

Summary of main results

Admission avoidance hospital at home probably makes little or no difference to risk of death at six months' follow-up and to readmission to hospital after discharge from hospital at home or inpatient care within 3 to 12 months (range of follow-up times from the included studies), and probably reduces the likelihood of relocating from home to residential care at six months. Admission avoidance hospital at home probably results in little to no difference in patient-reported health status, and the evidence suggests that it may increase patient satisfaction and reduce hospital length of stay; that total length of stay for hospital at home may be greater than for those allocated to hospital; and that hospital at home can be less costly than in-hospital care (Summary of findings 1).

Patients valued the quality of communication and personal care received in a hospital at home setting (Shepperd 2021; Wilson 1999). However, the increased satisfaction reported by patients must be balanced against the potential burden on caregivers; for example, interviews with caregivers showed that their contributions might be required to facilitate an episode of hospital at home (Makela 2020), and that this can place an additional burden on families. Comparing cost data from the different studies was limited by the different methods used to cost resources, and follow-up times that ranged from 1 to 12 months. Three trials conducted a full economic evaluation (Jones 1999 for Wilson 1999; Singh 2022 for Shepperd 2021; and Patel 2004 for Kalra 2000), reporting that hospital at home may lead to a small reduction in health service cost, a reduction in societal costs, and can be a cost-effective alternative to hospital admission for select groups of patients.

There was some variation in the way the admission avoidance hospital at home services operated that reflected different health systems, existing services available, and financing. Services admitted patients directly from the community (Harris 2005; Kalra 2000; Vianello 2013; Wilson 1999), outpatients (Talcott 2011), and from an accident and emergency department or medical assessment unit (Andrei 2011; Caplan 1999; Corwin 2005; Davies 2000; Echevarria 2018; Levine 2018; Levine 2020; Mendoza 2009; Nicholson 2001; Ricauda 2004; Ricauda 2008; Richards 2005; Shepperd 2021; Tibaldi 2004; Tibaldi 2009). Six trials evaluated interventions where the patient could be living alone, and five trials required a caregiver to be either living with the patient or nearby. This variation reflects the nature of complex interventions (i.e. similar to stroke units, case management, telemedicine), and we did not combine data from studies with a high level of clinical heterogeneity. There were some important common features across the different hospital at home services; these included access to a doctor, co-ordinated care provided by a multidisciplinary team, the provision of 24-hour cover if required, and a safe home environment being a requirement for the provision of hospital at home. Inevitably, hospital at home does not function as an isolated intervention, with the organisation of services reflecting local health systems, workforce, and available social care services. For some countries, integrating hospital at home into existing services is the most efficient way to deliver these services.

Admission avoidance hospital at home (Review)

Overall completeness and applicability of evidence

The evidence indicates that admission avoidance hospital at home may provide an effective alternative to inpatient care for a select group of patients requiring hospital admission. The majority of the included trials recruited participants who were older, with an average age that ranged from 70 to over 80 years, and who had experienced a medical event that required admission to hospital. All trials but one, [Andrei 2011](#), were conducted in high-income countries. Eight trials excluded patients who did not have continuous family support ([Caplan 1999](#); [Mendoza 2009](#); [Ricauda 2004](#); [Ricauda 2008](#); [Richards 2005](#); [Tibaldi 2004](#); [Tibaldi 2009](#); [Vianello 2013](#)). Four trials reported the number of participants recruited from ethnic minority groups; this ranged from 14% to 20% of all recruited participants ([Corwin 2005](#); [Levine 2020](#); [Richards 2005](#); [Talcott 2011](#)). In one trial, hospital at home included remote monitoring for heart rate, respiratory rate, telemetry, movement, falls, and sleep via a small skin patch; cost was the primary outcome ([Levine 2020](#)), and the study was stopped early by the funder (who was also the service provider) due to the cost benefit of the intervention.

The 20 trials included in this review were conducted in Australia, Italy, New Zealand, Romania, Spain, the UK, and the USA. There is growing interest from other health systems in testing the delivery of hospital-level care in the home. For example, in Singapore a large study that seeks to recruit 2000 participants is under way ([Chong 2022](#); [NCT04330378](#)), and a large hospital in Pune, India expects to increase its capacity by 40% to 60% using remote patient monitoring ([Mernin 2021](#)). A large hospital in Bangkok, Thailand has also set up an @Home service, suitable for patients after surgery or acute illness, patients with chronic conditions who need regular follow-up, and the dependent elderly ([Bumrungrad 2023](#)). Such services were also set up in the Philippines during COVID-19 ([CNN Philippines 2021](#)). Additional large, high-quality randomised trials will improve the certainty of the evidence and generalisability of these findings, and be a valuable guide to the development of out-of-hospital services to increase the capacity of health systems.

We defined admission avoidance hospital at home as: a service that can avoid the need for hospital admission by providing active treatment by healthcare professionals in the patient's home for a condition that would otherwise require acute hospital inpatient care, and always for a limited time period. All of the included studies met these criteria, and the evidence applies to services that also meet these criteria and do not provide long-term care, outpatient care, or self-administration of treatment. The studies varied in the amount of time that patients were in the emergency department before being admitted to hospital at home or a hospital bed; this was due to the type of illness and severity (and was not often analysed) and the ongoing demands on the health system in question. We did not apply a time threshold in the emergency room for the study to qualify as admission avoidance. If we had, it would likely have resulted in the exclusion of patients in the most pressured health systems, where evidence is arguably most needed, and have risked imposing an artificial time limit that isn't experienced on the ground, and thus limited the applicability of the evidence.

Hospital at home services inevitably place demands on those who live with the person receiving care, and family and friends who live elsewhere. Safety in the home, cultural considerations, and health problems experienced by the main carer pose further challenges

([Simon 2022](#)). An additional concern is inequality in the resources available to unpaid carers across different populations, which might increase the potential burden of receiving hospital at home ([Vlachantoni 2012](#)). A Cochrane qualitative evidence synthesis of factors that influence the implementation of hospital at home reports in detail on the barriers that limit implementation, as well as factors that support the implementation of sustainable hospital at home services ([Wallis 2024](#)). A limitation of the trials included in this review is that few reported if deaths occurred during the hospital at home admission, and if they were unexpected and related to the hospital at home intervention. The reason for this is likely the small sample size of many of the studies, and early death being a rare event. Mortality occurring during an episode of hospital at home or hospital (control group) admission might not be related to hospital at home or hospital care, and the cause would have to be assessed case by case. The cause of such adverse events was not always clearly reported in the included studies; further investigation would provide clarity on the causes of death and any links with the intervention.

Certainty of the evidence

While we assessed the overall risk of bias as low, most of the included studies were small. [Shepperd 2021](#) was the largest trial, recruiting 1032 participants who contributed to the analysis. The meta-analysis for the main outcome included a subgroup of five trials recruiting participants with similar conditions (older patients with a mix of medical conditions, excluding stroke) to limit heterogeneity. We downgraded the certainty of the evidence for mortality due to imprecision of the estimate: the result could be consistent with hospital at home being associated with both higher or lower risk of mortality. We downgraded for readmission to hospital and relocating to residential care, because the studies evaluated these outcomes at different lengths of follow-up, therefore the comparison was indirect. We downgraded for patient satisfaction because only 35% of the studies evaluated this outcome, and patients/researchers were not blinded. We downgraded for patient self-reported health status due to non-blinding, and for length of stay because the time frame for measuring this outcome differed among studies, and the estimates covered a wide range. We downgraded for cost because only three trials did a full cost analysis ([Kalra 2000](#); [Shepperd 2021](#); [Wilson 1999](#)).

Potential biases in the review process

We limited publication bias by conducting an extensive search that included different databases of published articles and sources of unpublished literature; this was facilitated by a long-established international network of people working in the field who alert us to new randomised controlled trials. Three review authors screened the search results of potentially eligible studies to reduce the risk of missing any eligible studies. To check that inclusion criteria had been applied consistently, eligibility of studies was discussed with the review team. As an author of one of the included studies ([Shepperd 2021](#)), review author SS was not involved in assessing their own study for inclusion, risk of bias assessment, or data extraction.

Admission avoidance hospital at home (Review)

Agreements and disagreements with other studies or reviews

Other reviews have looked at the effect of hospital at home schemes for end-of-life care (Shepperd 2021), and hospital at home for early discharge (Gonçalves-Bradley 2017). A review of a few studies of end-of-life care at home found that such programmes increase the chance of dying at home rather than in hospital, and patient satisfaction may be higher at one-month follow-up (Shepperd 2021). A review of early discharge hospital at home services found insufficient evidence for economic benefit, or improved health outcomes (Gonçalves-Bradley 2017). The search for this review was updated in March 2020 and identified no new studies.

Systematic reviews of hospital at home services for patients with specific conditions, such as COPD and heart failure, have been published (Jeppesen 2012; Qaddoura 2015). For patients with COPD, it was reported that hospital at home reduced the number of readmissions when compared with hospital care, with uncertain evidence for mortality, health-related quality of life, cost, and clinical outcomes (Jeppesen 2012). A review of a few studies that specifically recruited patients with heart failure found a slight increase in time to readmission, improved health-related quality of life, and reduced index costs, with limited evidence for mortality for those allocated to hospital at home. The authors judged these studies to be of modest quality (Qaddoura 2015). A systematic review of studies of hospital at home for chronic disease identified nine studies: five trials of COPD, two of heart failure, one of stroke, and one of neuromuscular disease (Arsenault-Lapierre 2021). We included all studies included in the Arsenault-Lapierre 2021 review in the current review update except for Hernandez 2003, which did not compare admission avoidance hospital at home with inpatient care. In Hernandez 2003, patients who required immediate hospitalisation were excluded, and the control group was evaluated by a physician who decided on inpatient admission or discharge. The review found no significant difference in mortality for a range of follow-up times, and a lower risk of readmission in the hospital at home group, using the longest follow-up time for each study. In addition, similar to the current review, Arsenault-Lapierre 2021 reported that length of treatment was longer in the hospital at home group, and relocation to residential care was less likely in the hospital at home group than in the in-hospital group; study authors did not analyse mortality occurring during the hospital or hospital at home admission.

AUTHORS' CONCLUSIONS

Implications for practice

Admission avoidance hospital at home, with the option of transfer to hospital, may provide an effective alternative to inpatient care for selected patients who require hospital admission. The 20 trials included in this review were conducted in several different countries. Although the health systems in these countries vary with respect to the way healthcare financing is structured, the policy objectives are the same, with admission avoidance hospital at home being provided to control costs and reduce demand for inpatient hospital beds (Aviv 2021; Naik 2006; Oliver 2021). The level of primary care in a country, and the enthusiasm of local clinicians and healthcare managers, may determine the degree to which admission avoidance hospital at home operates as an outreach model or is run by supplementing existing primary care

services. Other aspects that might vary by health system include the level of integration with existing services to avoid duplication of services, for example using existing out-of-hours services as in a single-payer system with free access at the point of care versus setting up a new out-of-hours service for patients that do not have access to this through their usual healthcare coverage (such as in a multipayer health system). Admission avoidance hospital at home may not completely substitute for hospital, as hospital admission remains an option if required, for example patients whose condition unexpectedly deteriorated or who could no longer be managed at home had access to transfer to a traditional acute hospital ward. Policymakers should consider what type of hospital care is planned to be substituted with hospital at home, and the impact this will have on cost-effectiveness.

The way health care for the control group is organised will have an impact on cost-effectiveness, for example the routine use of comprehensive geriatric assessment to structure hospital care will provide an additional layer of geriatrician-led multidisciplinary assessment and co-ordination of care that can improve outcomes (Ellis 2017). The entry criteria required that patients be clinically stable and not require specialist diagnostic investigation or emergency interventions. Patients eligible for the trials included in this review did not include those whose condition was so severe that death was an expected outcome. Furthermore, patients whose condition deteriorated or who could no longer be managed at home had access to hospital admission.

Although admission avoidance hospital at home provides an alternative to inpatient admission for some patients, the volume of such patients recruited to the included trials was comparatively low, and some of these patients required access to hospital services, which might make the closure of a ward or hospital in favour of hospital at home an unrealistic option. In Shepperd 2021, 37/687 (5%) participants allocated to hospital at home received required admission to hospital bed-based care, and 76/345 (22%) participants allocated to hospital instead received hospital at home care. This indicates that some patients require a greater intensity of care due to their condition deteriorating, that others have a preference for health care in their own home, and at times when no hospital beds were available for those randomised to hospital admission, hospital at home admission was required. Being less likely to be relocated to residential care at follow-up might be due to the location of the patient influencing the decision to move to residential care, or be related to the patient's maintaining their usual routines at home while avoiding some of the harms associated with the inpatient environment such as sleep deprivation, poor nutrition, confusion, and falls and infection risk (Mudge 2019). A reduction in relocating to residential care may contribute to cost savings from hospital at home.

Many of the studies in this review are over 10 years old and do not reflect the recent improvement of remote patient monitoring technology. These developments are advancing rapidly and may allow hospital at home to care for different groups of patients. However, there have been concerns about excluding patients based on their or their caregiver's low technological literacy (British Geriatrics Society 2022).

Admission avoidance hospital at home (Review)

Implications for research

Over the last 20 years the randomised evidence has grown from 1 to 20 trials, using a pragmatic randomised trial design that includes a process evaluation to inform real-world implementation.

Future research of admission avoidance hospital at home should assess the impact of hospital at home services in more disadvantaged populations, who are more likely to have a higher percentage of informal caregivers (Young 2005). Mortality should be measured, in particular during admission to hospital at home and hospital, along with transfer to hospital during a hospital at home admission, readmission to hospital after discharge from hospital at home or inpatient care, relocation to residential care at follow-up, and cost-effectiveness. Studies should clarify if mortality during the acute episode was assessed as related to the hospital at home intervention or hospital control and unexpected.

There is little evidence on the impact of hospital at home on patients, caregivers and their networks, despite the potential for them to have a significant role when health care is being delivered in the patient's home. A qualitative study linked to the randomised trial by Shepperd 2021 (Makela 2020) describes how patients and caregivers facilitate the delivery of hospital at home care, and this includes monitoring the patient. A recent study found that caregiver burden should be a key aspect to assessing appropriate social support during hospital at home (Levine 2021). Additional evidence on how staff experience hospital at home, the training required, and how roles evolve would help with workforce planning (e.g. Karacaoglu 2021; Leary 2022), and if hospital at home services represent a shift in care provision to patients' families and lower skilled workers (Batt 2023). A recent survey identified several domains for future research, including defining the type of hospital at home care, defining optimal study outcomes, patient and caregiver experience, the education of hospital at home clinicians, and the use of technology and telehealth, among others (Leff 2022). Other important outcomes for future research should include the assessment of unintended impacts, person-centred care, advanced care planning, and the impact on unpaid carers and their networks. As hospital at home services are more widely implemented, evidence on the impact on caregiver outcomes that includes burden, experience, satisfaction, and quality of life becomes increasingly important.

The potential for admission avoidance hospital at home to increase the capacity of health systems was explored during the COVID-19 pandemic (Aviv 2021; Nundy 2020; Oliver 2021). Further study has been done regarding 'virtual wards' and remote monitoring in this context (Thornton 2020), with a review of 27 studies finding that

patient/carer training was a determining factor of success, but there was uncertainty of evidence around patient safety or deterioration (Vindrola-Padros 2021). This is another area that requires more research, as there is a risk that remote monitoring might not be used effectively.

ACKNOWLEDGEMENTS

We thank peer reviewers for their comments on previous versions (updates and the first version) of this review, and acknowledge the following individuals for providing individual patient data for the 2008 version: Dr Roger Harris and Joanne Broad, Dr Lalit Kalra, Dr Aimonino Ricauda, and Professor Andy Wilson. Robert M Angus for collaborating on previous versions of the review, and Nia Roberts and Paul Miller for updating and conducting the searches.

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Andrei 2011

Study characteristics

Methods	Parallel randomised trial
Participants	Setting: Romania People with chronic heart failure who had deteriorated at a minimum of 1 week prior to recruitment. Number of participants in each group was not reported, a total of 45 participants recruited.
Interventions	Admission avoidance hospital at home; the first 48 hours of treatment was in the emergency department
Outcomes	Mortality, biological measures, and cost
Notes	Follow-up at 1, 3, 6, and 12 months Funding: the study was published as an abstract, details not reported Conflicts of interest: details not reported Ethical approval: details not reported

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	The study was published as an abstract, details not reported
Allocation concealment (selection bias)	Unclear risk	The study was published as an abstract, details not reported
Baseline outcome measurements (selection bias)	Unclear risk	The study was published as an abstract, details not reported
Baseline characteristics (selection bias)	Unclear risk	The study was published as an abstract, details not reported

Admission avoidance hospital at home (Review)

Andrei 2011 (Continued)

Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	Not reported
Blinding of outcome assessment (detection bias) Objective outcomes	Unclear risk	Methods not reported
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	The study was published as an abstract, details not reported
Selective reporting (reporting bias)	Unclear risk	The study was published as an abstract, details not reported

Caplan 1999
Study characteristics

Methods	Parallel randomised trial Study conducted between October 1995 and February 1997.
Participants	Setting: Australia Range of acute conditions requiring admission to hospital; participants recruited from casualty Number recruited: hospital at home: 51; hospital: 49
Interventions	Hospital community outreach team Type of service: hospital community outreach team. Clinical responsibility by GP, or hospital doctor if GP declined
Outcomes	Functional status, mental status, clinical complications, patient and caregiver satisfaction, GP views
Notes	Follow-up: 1 and 6 months Funding: not reported Conflicts of interest: not reported Ethical approval: hospital ethical committee

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random numbers, stratified by participant's residence and if they had a deep vein thrombosis

Admission avoidance hospital at home (Review)

Caplan 1999 (Continued)

Allocation concealment (selection bias)	Low risk	Sealed envelope
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for functional and mental status, and diagnoses; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of treatment and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	Unclear risk for functional status, mental status, clinical complications, patient and caregiver satisfaction, GP view
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for mortality, readmission
Incomplete outcome data (attrition bias) All outcomes	Low risk	No loss to follow-up reported
Selective reporting (reporting bias)	Unclear risk	Insufficient information to allocate low or high risk

Corwin 2005
Study characteristics

Methods	Parallel randomised trial Study conducted between July 2002 and June 2003.
Participants	Setting: New Zealand Patients with cellulitis Number recruited: treatment: 98, control: 96 Ages, mean (SD): T: 54.6 (20.6), C: 48.4 (19) European: T: 77/98 (79%), C: 78/96 (81%) Maori: T: 10/98 (10%), C: 5/96 (5%) Pacific: T: 2/98 (2%), C: 1/96 (1%) Other: T: 9/98 (9%), C: 13/96 (12%)
Interventions	Hospital at home admission avoidance from the emergency department. Run by Pegasus Health, an independent practitioner's association for 230 GPs in Christchurch, New Zealand. Care provided by GP and community care nursing staff. Patients required IV antibiotics for cellulitis.

Admission avoidance hospital at home (Review)

Corwin 2005 (Continued)

Outcomes	Advancement of cellulitis, readmission, days on IV antibiotics, functional outcomes (SF-36), patient satisfaction
Notes	Follow up: 3 and 6 days Funding: Pegasus Health Conflicts of interest: none declared Ethical approval: local ethical committee

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomisation list produced by SAS code
Allocation concealment (selection bias)	Low risk	Telephone randomisation service
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for functional outcomes; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of treatment and control groups are reported and similar for main characteristics
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	Unclear risk for pain, functional and physical health (SF-36), and satisfaction
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for advancement of cellulitis
Incomplete outcome data (attrition bias) All outcomes	Low risk	3 from each group excluded at follow-up
Selective reporting (reporting bias)	Unclear risk	Insufficient information to allocate low or high risk

Davies 2000
Study characteristics

Methods	Parallel randomised trial Study conducted between February 1998 and August 1999.
Participants	Setting: UK

Admission avoidance hospital at home (Review)

Davies 2000 (Continued)

Patients with chronic obstructive airways disease

Number recruited: hospital at home: 100, hospital: 50

Interventions	Hospital at home Type of service: admission avoidance from A&E. Care provided by outreach specialist nurses and GP and community nurses if required.
Outcomes	Respiratory function, readmission, quality of life
Notes	Few details on measure of quality of life Follow up: 2 weeks and 3 months Funding: North Mersey Community (NHS) Trust and University of Liverpool (UK) Conflicts of interest: none declared Ethical approval: district ethical committee This author contributed IPD for a previous update of this review (Shepperd 2016a).

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Ratio of 2:1 (hospital at home: hospital)
Allocation concealment (selection bias)	Low risk	Opaque, sealed envelopes
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for respiratory function; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding of participants and personnel not possible Hospital readmission was a primary outcome, with decision to admit made by hospital staff
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	A small group of participants completed the St George's Respiratory Questionnaire
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for admission to hospital, changes in FEV1 score
Incomplete outcome data (attrition bias) All outcomes	Low risk	Loss to follow-up: hospital at home: 7/100; hospital: 5/50
Selective reporting (reporting bias)	Low risk	All outcomes reported (received trial data set)

Admission avoidance hospital at home (Review)

Echevarria 2018

Study characteristics

Methods	<p>Parallel randomised trial</p> <p>Study conducted between June 2014 and January 2016.</p>
Participants	<p>Setting: UK</p> <p>Patients aged ≥ 35 years, admitted to hospital with COPD exacerbation and low mortality risk. Those with life expectancy < 1 year due to illness other than COPD, long-term ventilation, and coexistent secondary diagnosis necessitating admission were excluded.</p> <p>Number recruited: hospital at home: 62; usual care: 58 (analysed: hospital at home: 60; usual care: 58)</p> <p>Mean age (SD): T: 71 (9.6), C: 68.7 (10.5)</p> <p>Female: T: 32/60 (53%), C: 30/58 (52%)</p> <p>Approximately 1/5 of participants also had ischaemic heart disease and depression.</p>
Interventions	<p>The intervention consisted of once- or twice-daily visits from a respiratory specialist nurse, under remote supervision from a respiratory consultant. An emergency contact number allowed patients to contact the team 24/7. Patients were monitored daily, and blood sampling was taken as required. Other available services included oral and IV therapies, acute controlled oxygen therapy, physiotherapy, psychology, occupational therapy, and formal social care.</p> <p>Comparison: usual hospital care</p>
Outcomes	<p>Main outcomes: health and social care costs over 90 days (non-inferiority analysis)</p> <p>Other outcomes: survival; all-cause and respiratory readmission rates; bed days over a) acute period of care, and b) postdischarge to 90 days; caregiver and patient preference; COPD exacerbations; unplanned health resource use; HADS score; quality of life; caregiver burden; perceptions of health care of patients and their caregivers and health professionals regarding the use of the clinical score for group allocation</p>
Notes	<p>Follow-up: 90 days</p> <p>Trial registry: ISRCTN29082260</p> <p>Funding: National Institute for Health Research (NIHR, UK)</p> <p>Conflicts of interest: "SCB reports grants from NIHR: Research for Patient Benefit Programme, during the conduct of the study; HTA funding, grants from Philips Respironics and Pfizer Open Air, personal fees from Pfizer and AstraZeneca, outside the submitted work. JG reports grants from NIHR Research for Patient Benefit, during the conduct of the study. CE, GJG, TH, AJS and JS have no competing interests to declare."</p> <p>Ethical approval: local ethics committee</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "Allocation to HAH or UC was based on 1:1 randomisation, performed by minimisation undertaken by an external, independent agency (sealedenvelope.com)"

Admission avoidance hospital at home (Review)

Echevarria 2018 (Continued)

Allocation concealment (selection bias)	Low risk	Quote: "The researchers were blind to the method of allocation for individual patients. For the primary cost analysis, the health economist was blinded to group allocation"
Baseline outcome measurements (selection bias)	Low risk	Comment: similar proportion of ECOPD treatment prior to admissions, Hospital Anxiety and Depression score, COPD assessment tool, and utility scores (EQ-5D-5L)
Baseline characteristics (selection bias)	Low risk	Quote: "Groups were well matched with respect to minimisation indices"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "For the primary cost analysis, the health economist was blinded to group allocation."
Blinding of outcome assessment (detection bias) Subjective outcomes	Low risk	Comment: subjective outcome was 'stated preference for HAH care day 14' (subjective to patient, did not require subjective judgement by researcher) Quote: "Patients in both arms maintained a diary of all health and social care visits and attendances, and were phoned every 2 weeks to prompt completion and collect data."
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Quote: "For the primary cost analysis, the health economist was blinded to group allocation."
Incomplete outcome data (attrition bias) All outcomes	Low risk	Comment: sensitivity analysis carried out for missing data
Selective reporting (reporting bias)	Low risk	Comment: outcomes are consistent between trial registry and published results.

Harris 2005

Study characteristics

Methods	Parallel randomised trial Dates of study not reported.
Participants	Setting: New Zealand Patients had a broad range of diagnoses: fractures (28%); miscellaneous medical problems (18%); respiratory problems (16%); stroke and neurological diagnoses (14%); falls and injuries (11%); cardiac diagnoses (8%); and rehabilitation and other problems (5%). Number recruited: hospital at home: 39, hospital: 37
Interventions	Operated as a hospital outreach programme under the management of Auckland Hospital from the emergency department or acute assessment ward. A nurse-led multidisciplinary team (physiotherapy, occupational therapy, social work) co-ordinated care and rehabilitation for the patient within the patient's own home. There was a daily nursing review. Clinical responsibility was held by a dedicated hospital at home registrar, a consultant geriatrician, and in some cases the patient's GP, with 24-hour on-call medical cover. The service provided care 7 days a week with 10 hours of nursing care a day

Admission avoidance hospital at home (Review)

Harris 2005 (Continued)

available, and a 24-hour live-in home caregiver if required. There was a daily nursing review, and a discharge handover to ongoing support services.

The study included 2 treatment groups and a control (hospital) group. 1 treatment group was an "admission prevention" group and the other an "early discharge" group. We received IPD for the admission prevention and control groups only from the trialist.

Outcomes	Activities of daily living, cognitive function, instrumental activities of daily living
Notes	<p>Follow-up: 90 days</p> <p>Funding: Northern Regional Health Authority (New Zealand)</p> <p>Conflicts of interest: not reported</p> <p>Ethical approval: local ethics committee</p> <p>This author contributed IPD for a previous update of this review (Shepperd 2016a).</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated randomisation service
Allocation concealment (selection bias)	Low risk	Telephone randomisation service
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for activities of daily living, instrumental activities of daily living, and cognitive functioning; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding of participants and personnel not possible Research staff did not make decision to admit to hospital
Blinding of outcome assessment (detection bias) Subjective outcomes	Low risk	Trained researchers not involved in patient care assessed participants for functional independence (FIM), cognitive function (MMSE), and instrumental activities of daily living (OARS)
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for mortality, readmission, and measurement and valuation of costs
Incomplete outcome data (attrition bias) All outcomes	Low risk	Participants withdrawing: hospital at home: 4/143; hospital: 10/124
Selective reporting (reporting bias)	Low risk	All outcomes reported (received trial data set)

Admission avoidance hospital at home (Review)

Kalra 2000
Study characteristics

Methods	Parallel randomised trial Study conducted between April 1995 and October 1999.
Participants	Setting: UK Patients recovering from a moderately severe stroke Number recruited: hospital at home: 153; stroke unit care: 152; hospital care: 152 Median age (IQR): T: 75 (72 to 84), C: 77.7 (67 to 83) Living alone: T: 50/148 (34%), C: 50/149 (34%)
Interventions	Hospital outreach admission avoidance multidisciplinary with joint care from community services
Outcomes	Mortality, institutionalisation, level of independence, activities of daily living, treatment inputs, readmission, hospital length of stay, cost
Notes	Follow-up: 3, 6, and 12 months Funding: NHS R&D Executive's Health Technology Assessment Programme; Stroke Association; Bromley Health Authority (UK) Conflicts of interest: not reported Ethical approval: local ethics committee

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Block randomisation, computer-generated random numbers
Allocation concealment (selection bias)	Low risk	Telephone randomisation
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for level of independence and activities of daily living; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding of participants and personnel not possible Primary outcome: death
Blinding of outcome assessment (detection bias) Subjective outcomes	Low risk	A trained researcher, independent of the health care provided and unaware of treatment allocation, assessed functional status (Barthel and Rankin scale)
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for mortality, institutionalisation, resource use and cost

Admission avoidance hospital at home (Review)

Kalra 2000 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	Loss to follow-up: hospital at home: 9/144; hospital: 3/152
Selective reporting (reporting bias)	Low risk	All outcomes reported (received trial data set)

Levine 2018
Study characteristics

Methods	Parallel pilot randomised trial Study conducted between September and November 2016.
Participants	Setting: USA Patients aged ≥ 18 years, attending the emergency department with a primary diagnosis of any infection, heart failure exacerbation, COPD exacerbation, or asthma exacerbation. Those residing in a facility that provided on-site medical care or who were at high risk for clinical deterioration were excluded. Number recruited: hospital at home: 9; usual care: 11 Median age (IQR): T: 65 (28), C: 60 (29) Female: T: 2/9 (22%), C: 8/11 (73%) Participants had on average 6 comorbidities and took 9 medications.
Interventions	The intervention was tailored to the patient's needs. There was at least 1 daily visit from an attending general internist and 2 daily visits from a home health registered nurse; additional services included medical meals and the services of a home health aide, social worker, physical therapist, and/or occupational therapist. Home services included oxygen and respiratory therapies, radiology, and point-of-care blood diagnostics; patients were remotely monitored for heart rate, respiratory rate, telemetry, movement, falls, and sleep via a small skin patch. Control group: usual hospital care; patients were also monitored using the same skin patch.
Outcomes	Main outcome: total cost of the hospitalisation Other outcomes: length of stay, readmissions, healthcare use, quality of life, activities of daily living, satisfaction with care
Notes	Follow-up: 30 days Funding: Partners HealthCare Population Health Management; Institutional National Research Service Award; Ryoichi Sasakawa Fellowship Fund (USA) Conflicts of interest: none reported Ethical approval: approved by local ethical committee Trial registry: NCT02864420

Risk of bias

Bias	Authors' judgement	Support for judgement
------	--------------------	-----------------------

Admission avoidance hospital at home (Review)

Levine 2018 (Continued)

Random sequence generation (selection bias)	Low risk	Quote: "stratified by condition with randomly selected block sizes between 4 and 6"
Allocation concealment (selection bias)	Low risk	Quote: "allocation concealment via sealed envelopes"
Baseline outcome measurements (selection bias)	Unclear risk	Comment: participants allocated to the control group reported more depression symptoms and lower self-assessed quality of life. There was little or no difference between groups for hospital admission and ED visits in the past 6 months
Baseline characteristics (selection bias)	Unclear risk	Comment: participants allocated to the control group were younger, more likely to be female and speak English, more educated and less likely to be privately insured. Although these were sub-threshold values, the sample is very small.
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible.
Blinding of outcome assessment (detection bias) Subjective outcomes	Low risk	No subjective outcomes.
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Quote: "All measures were derived from the EHR, except falls, physical activity, and sleep, which were observed via the skin patch."
Incomplete outcome data (attrition bias) All outcomes	Low risk	Comment: very low attrition.
Selective reporting (reporting bias)	Unclear risk	Comment: primary and secondary outcomes are the same as per trial registry. There are other outcomes mentioned in the trial registry but not in the publication.

Levine 2020
Study characteristics

Methods	<p>Parallel pilot randomised trial</p> <p>Study conducted between June 2017 and January 2018; follow-up ended on 17 February 2018.</p>
Participants	<p>Setting: USA</p> <p>Patients aged ≥ 18 years, attending the emergency department with a primary diagnosis of any infection, heart failure exacerbation, COPD exacerbation, or asthma exacerbation. Those residing in a residential or rehabilitation facility or who were at high risk for clinical deterioration were excluded.</p> <p>Number recruited: hospital at home: 43; usual care: 48 (all randomised)</p> <p>Median age (IQR): T: 80 (19), C: 72 (23)</p> <p>Female: T: 15/43 (35%), C: 18/48 (38%)</p>

Admission avoidance hospital at home (Review)

Levine 2020 (Continued)

Patients were generally frail and chronically ill and used hospital care frequently.

Interventions	<p>The intervention was tailored to the patient's needs. There was at least 1 daily visit from an attending general internist and 2 daily visits from a home health registered nurse; additional services included medical meals and the services of a home health aide, social worker, physical therapist, and/or occupational therapist. Home services included oxygen and respiratory therapies, radiology, and point-of-care blood diagnostics; patients were remotely monitored for heart rate, respiratory rate, telemetry, movement, falls, and sleep via a small skin patch. Care was available 24/7 from the attending physician.</p> <p>Control group: usual hospital care; sleep was monitored using the same skin patch as the intervention group.</p>
Outcomes	<p>Main outcome: total cost of the hospitalisation</p> <p>Other outcomes: length of stay, readmissions, healthcare use, quality of life, activities of daily living, satisfaction with care</p>
Notes	<p>Follow-up: 30 days</p> <p>Funding: Partners HealthCare Center for Population Health and internal departmental funds (USA)</p> <p>Conflicts of interest: "Dr. Levine reports grants from Biofourmis outside the submitted work. Dr. Blanchfield reports consulting income from Verily, GreyBird Ventures, and Atlas5D outside the submitted work. Dr. Schnipper reports grants from Mallinckrodt Pharmaceuticals and Portola Pharmaceuticals outside the submitted work."</p> <p>Ethical approval: approved by local ethical committee</p> <p>Trial registry: NCT03203759</p> <p>The study was stopped early after enrolling 91 patients (76% of intended sample) "in light of local operational needs to quickly increase home hospital capacity after positive interim outcomes were presented to hospital leadership".</p> <p>63% of patients approached and possibly eligible refused to participate.</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	An outside statistician generated the randomization using SAS (SAS Institute). Randomization was stratified by infection, heart failure, chronic obstructive pulmonary disease or asthma, and other diagnosis; block sizes between 4 and 6 were randomly selected,
Allocation concealment (selection bias)	Low risk	Comment: allocation was concealed via sealed opaque envelopes.
Baseline outcome measurements (selection bias)	Low risk	Comment: the primary outcome was the direct cost of an acute care episode, data were obtained from the electronic record
Baseline characteristics (selection bias)	Unclear risk	Comment: a few differences between groups, with the largest difference being for the numbers who recorded having a home health aide at baseline: HAH 17/43 (40%) vs control 10/48 (21%)
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Comment: patients, study staff and physicians were not blinded to allocation status.

Admission avoidance hospital at home (Review)

Levine 2020 (Continued)

Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	Comment: unclear risk of bias for unblinded assessment of physical activity, patient experience, and quality during the acute care episode
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Comment: the primary outcome was the direct cost of an acute care episode; secondary outcomes were health care use, physical activity, patient experience, safety (medication and delirium), and quality of care during the acute care episode
Incomplete outcome data (attrition bias) All outcomes	Low risk	Comment: "If patients could not be reached 30 days after discharge (8 total patients, 1 in the home group and 7 in the control group), we used EHR data alone to estimate health care use and readmission rates and did not measure patient experience." (page 79)
Selective reporting (reporting bias)	Low risk	Comment: outcomes are consistent between trial registry and published results.

Mendoza 2009
Study characteristics

Methods	Parallel randomised trial Study conducted between May 2006 and March 2007.
Participants	Setting: Spain Patients in A&E with acute decompensation of chronic heart failure Inclusion criteria: > 65 years of age, with heart failure for at least 12 months prior to study, NYHA functional class II or III prior to acute episode, all-day supervision available, telephone, < 10 kilometres from hospital Age > 65 years, mean age 79. 29% female in hospital arm, 51% female in hospital at home arm Number recruited (between May 2006 and March 2007): hospital at home: 37; hospital: 34
Interventions	Admission avoidance hospital at home; patients admitted from emergency departments, hospital outreach model. Hospital at home nurse visited within 12 to 24 hours of admission to hospital at home and then daily visits. Care available between 8 a.m. and 9 p.m.; patients called emergency services outside these hours. Hospital specialist visited daily or every other day, depending on patient's condition. Control group: admitted to hospital
Outcomes	Mortality, readmission, functional status, general health status, length of stay, costs
Notes	Follow-up: 1 year after discharge Funding: Caja Vital Kutxa (Spain) Conflicts of interest: none declared Ethical approval: approved by the hospital ethical committee This author contributed IPD for a previous update of this review (Shepherd 2016a).

Risk of bias
Admission avoidance hospital at home (Review)

Mendoza 2009 (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation described as "externally generated sequence."
Allocation concealment (selection bias)	Low risk	Random sequence hidden from the physician until patient had consented to participate
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for functional status and general health status; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	A trained researcher, independent of the health care provided, assessed functional status (Barthel Index), health-related quality of life (SF-36)
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for death, readmission
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	9 of 80 did not complete the study (2 in hospital at home group, 7 in hospital group)
Selective reporting (reporting bias)	Unclear risk	Insufficient information to allocate low or high risk

Nicholson 2001
Study characteristics

Methods	Parallel randomised trial Study conducted between October 1999 and October 2000.
Participants	Setting: Australia Patients with COPD Inclusion criteria: age > 45 years, COPD, current or ex-smoker, FEV1 < 60% predicted, admission requested by GP or OPD clinic staff or ED staff, telephone at home Number recruited: hospital at home: 13; hospital: 12
Interventions	Hospital at home (discharge from emergency department) Patients retained in patient status and received clinical supervision from hospital specialist, and hospital had legal and financial responsibility; also received care from GP, community nursing, and domiciliary care. Hospital medical staff provided 24-hour telephone support.

Admission avoidance hospital at home (Review)

Nicholson 2001 (Continued)

Outcomes	Cost to the health service
Notes	<p>Follow-up: duration of care in hospital at home or inpatient care</p> <p>Funding: the Commonwealth Department of Health and Aged Care, National Demonstration Hospitals Program Phase 3</p> <p>Conflicts of interest: not reported</p> <p>Ethical approval: not reported</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Random sequence generation not described
Allocation concealment (selection bias)	Unclear risk	Allocation concealment not described
Baseline outcome measurements (selection bias)	Unclear risk	Baseline outcome measurements not reported
Baseline characteristics (selection bias)	Unclear risk	Baseline characteristics of the study and control groups not reported
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	None reported
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for resource use and cost
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Insufficient information to allocate low or high risk
Selective reporting (reporting bias)	Unclear risk	Insufficient information to allocate low or high risk

Ricauda 2004

Study characteristics

Methods	<p>Parallel randomised trial</p> <p>Participants recruited from January 1997 to February 1998.</p>
Participants	Setting: Italy

Admission avoidance hospital at home (Review)

Ricauda 2004 (Continued)

Patients recovering from a stroke

Eligibility criteria: patients admitted to hospital within 24 hours of the onset of symptoms and evaluated for at least 24 hours

Age (IQR): 76 to 88, median 82

Number recruited: hospital at home: 60; hospital: 60

Interventions	Hospital outreach admission avoidance. 24-hour care available from a multidisciplinary team: physiotherapist, occupational therapist, nursing, hospital geriatrician, social worker, speech therapist, psychologist
Outcomes	Length of treatment, mortality, activities of daily living, functional impairment, depression, costs
Notes	Follow-up: 6 months External funding not reported. Conflicts of interest: not reported Ethical approval: obtained from the San Giovanni Battista Hospital ethics committee

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Block randomisation
Allocation concealment (selection bias)	Unclear risk	Not described
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for activities of daily living, functional impairment, and depression; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Low risk	Outcomes assessor blinded to the study allocation, and used validated measures of outcome
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Outcomes assessor blinded to the study allocation
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Withdrawals not reported
Selective reporting (reporting bias)	Unclear risk	Insufficient information to allocate low or high risk

Admission avoidance hospital at home (Review)

Ricauda 2008
Study characteristics

Methods	<p>Parallel randomised trial</p> <p>Study conducted between April 2004 and April 2005.</p>
Participants	<p>Setting: Italy</p> <p>Patients requiring acute hospitalisation for acute exacerbation of COPD; care supervision at home; telephone connection; living in the catchment area; family or social support</p> <p>Age (SD): T: 80.1 (3.2), C: 79.2 (3.1)</p> <p>Number recruited: hospital at home: 52; inpatient: 52</p>
Interventions	<p>Physician-led admission avoidance hospital outreach service; GHHS of a regional hospital.</p> <p>The home care programme emphasised patient and caregiver education about the disease, advice about smoking cessation, nutrition, management of activities of daily living and energy conservation, understanding and use of drugs, health maintenance, and early recognition of triggers of exacerbation that require medical intervention. In the first days after admission to GHHS, physicians and nurses visited each patient at home daily, then daily visits by the nurse and visits by the doctor every 2 to 3 days or less. Blood tests, electrocardiogram, spirometry, pulse oximetry, oxygen, IV fluids, antimicrobials and other medications, blood transfusions, surgical treatment for pressure ulcers were available.</p> <p>Control group: inpatient hospital care</p>
Outcomes	Mortality, readmission, health status, satisfaction, residential care, length of stay, resource use and cost, caregiver outcomes
Notes	<p>Follow-up: 6 months</p> <p>Funding: S. Giovanni Battista Hospital of Torino</p> <p>Conflict of interest: public funds of S. Giovanni Battista Hospital of Torino were used in this study. The editor-in-chief has reviewed the conflict of interest checklists provided by the authors and determined that none of the authors have any financial or any other kind of personal conflicts with this manuscript.</p> <p>Ethical approval: ethical approval was obtained from the hospital ethics committee.</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random numbers
Allocation concealment (selection bias)	Low risk	The project manager randomly allocated participants using a numbered set of sealed envelopes
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for health status; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar

Admission avoidance hospital at home (Review)

Ricauda 2008 (Continued)

Blinding of participants and personnel (performance bias) All outcomes	Low risk	Data collected by independent postgraduate physicians who were not involved in the care of patients or the research team
Blinding of outcome assessment (detection bias) Subjective outcomes	Low risk	Outcomes assessed by a postgraduate doctor not involved with delivery of health care, and blinded to the study allocation
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Outcomes assessed by a postgraduate doctor not involved with delivery of health care, and blinded to the study allocation
Incomplete outcome data (attrition bias) All outcomes	Low risk	No loss to follow-up
Selective reporting (reporting bias)	Low risk	Standard set of outcomes reported

Richards 2005
Study characteristics

Methods	Parallel randomised trial Study conducted between July 2002 and October 2003.
Participants	Setting: New Zealand Patients with community-acquired pneumonia Age: T: 50.1, C: 49.8 Number recruited: hospital at home: 24; hospital: 25
Interventions	Hospital at home: admission avoidance from emergency room. Run by Pegasus Health, an independent practitioner's association for 230 GPs in Christchurch, New Zealand. Care provided by GP and community care nursing staff.
Outcomes	Median number of days to discharge, days of IV antibiotics, functional outcomes, mortality, readmission, patient satisfaction, costs
Notes	Follow-up: 2 and 6 weeks Funding: not reported Conflicts of interest: none reported Ethical approval: local ethics committee Canterbury Ethics Committee, Christchurch, New Zealand

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random numbers

Admission avoidance hospital at home (Review)

Richards 2005 (Continued)

Allocation concealment (selection bias)	Low risk	Telephone randomisation
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for functional outcomes; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	Patient-rated symptoms, satisfaction
Blinding of outcome assessment (detection bias) Objective outcomes	Unclear risk	Days on IV antibiotics, admissions extracted from clinical records
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	6 exclusions after randomisation, no loss to follow-up
Selective reporting (reporting bias)	Unclear risk	Insufficient information to allocate low or high risk

Shepperd 2021
Study characteristics

Methods	Parallel randomised trial First participant was recruited 14 March 2015, last participant was recruited 18 June 2018.
Participants	Setting: UK Patients aged ≥ 65 years, who have been referred to the geriatrician-led admission avoidance hospital at home service and would otherwise require hospital admission for an acute medical event. Patients were excluded if they had acute coronary syndrome, suspected stroke, lived in residential settings, required palliative care, or were assessed as high risk. Age: T: 83.3 (7.0), C: 83.3 (6.9) Number recruited: hospital at home: 700; hospital: 355
Interventions	Intervention is geriatrician-led co-ordinated, multidisciplinary health care in the home, delivered by a team including nurses, physiotherapists, occupational therapists, and social workers who are either part of the primary healthcare team or dedicated staff and can refer the patient to other services as needed (e.g. mental health or social work services, pharmacy support). Health care was provided 7 days per week, and emergency medical cover was available 24 hours/day. Control group: hospital-based inpatient, with comprehensive geriatric assessment when available
Outcomes	Main outcome: living at home

Admission avoidance hospital at home (Review)

Shepperd 2021 (Continued)

Other outcomes: activities of daily living, cognitive impairment, delirium, mortality, new long-term residential care, quality of life, resource use, transfer to hospital

Notes

Follow-up: 6 and 12 months

Trial registry: [ISRCTN60477865](#)

Funding: NIHR Health Services and Delivery Research Programme (UK)

Conflicts of interest: none declared

Ethical approval: Research Ethics Committee England, Wales and Northern Ireland, and Scotland

Primary reference is *Annals of Internal Medicine* article.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "Randomization was stratified by site, sex, and cognitive status measured before randomization using the Informant Questionnaire on Cognitive Decline in the Elderly (IQCODE)"
Allocation concealment (selection bias)	Low risk	Quote: "Eligible participants who provided informed consent were randomly allocated to either CGA HAH or hospital admission using Sortition, a validated, secure online randomization system developed by the University of Oxford's Primary Care Clinical Trials Unit."
Baseline outcome measurements (selection bias)	Low risk	Comment: Patients had similar mean MoCA scores, Barthel scores, comorbidity, delirium, and EQ-5D-5L.
Baseline characteristics (selection bias)	Low risk	Comment: Patients had similar proportions of the presenting problems, diagnoses.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Comment: Main outcome (inverse of death or new admission to long-term residential care) is objective
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	Comment: Questionnaire outcomes collected by study staff aware of allocation.
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Comment: Main outcome (inverse of death or new admission to long-term residential care) is objective
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "Sensitivity analyses showed little or no change when missing data were imputed with different outcomes."
Selective reporting (reporting bias)	Low risk	Comment: Primary outcome was changed to be measured at 6 months not 12 months, agreed on by trial steering committee.

Admission avoidance hospital at home (Review)

Talcott 2011
Study characteristics

Methods	<p>Parallel randomised trial</p> <p>Study conducted between September 1994 and January 1999.</p>
Participants	<p>Setting: USA</p> <p>Participants: recruited from outpatients with postchemotherapy febrile neutropenia and assessed as low risk if there was no indication for hospitalisation other than fever and neutropenia (such as systemic hypotension, altered mental status, respiratory failure, or inadequate oral fluid intake during 24-hour observation; and had adequately controlled cancer)</p> <p>Age 20 to 81 years, median 47 years</p> <p>Number recruited: hospital at home: 47; inpatient: 66</p>
Interventions	<p>Admission avoidance hospital at home, patients recruited from outpatient clinic. Provided by commercial home care provider who agreed to provide protocol care for patients without out-of-pocket charges; daily visits by a home care nurse who followed a protocol/standard checklist and contacted the primary care physician if there were abnormal findings. Daily blood tests. 24-hour care available. Hospital specialist examined the patient 2 to 4 days following discharge and then at least weekly. Home IV available.</p> <p>Control group received care in oncology units in general hospitals.</p>
Outcomes	Major medical complications, readmission to hospital, quality of life
Notes	<p>Follow-up time for each episode was the resolution of fever, neutropenia, and any complications arising during the episode. Quality of life data were collected at the time of consent to join the study and as soon as possible after resolution of the episode.</p> <p>Funding: National Cancer Institute (USA)</p> <p>Conflicts of interest: authors indicated no potential conflicts of interest.</p> <p>Ethical approval: not reported</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated blocks of random numbers stratified by colony-stimulating factors, institution, and whether random assignment occurred on week-ends, holidays, or after hours
Allocation concealment (selection bias)	Low risk	Sealed envelopes
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for clinical characteristics and quality of life; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar for all main characteristics
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Any medical event requiring urgent diagnostic or therapeutic intervention. Predefined complications included systemic hypotension (systolic blood pressure > 90 mmHg), respiratory failure (partial pressure of oxygen < 60 torr adjusted for hyperventilation)

Admission avoidance hospital at home (Review)

Talcott 2011 (Continued)

Blinding of outcome assessment (detection bias) Subjective outcomes	Low risk	Predefined medical complications using blinded review
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for mortality and cost
Incomplete outcome data (attrition bias) All outcomes	Low risk	No participants lost to follow-up, 5 withdrawn/excluded (3 withdrew consent, 2 excluded as neutropenia had resolved at recruitment)
Selective reporting (reporting bias)	Unclear risk	Insufficient information to allocate low or high risk

Tibaldi 2004
Study characteristics

Methods	Parallel randomised trial Study conducted between February 1999 and April 2002.
Participants	Setting: Italy Patients: elderly with advanced dementia Mean age (SD): T: 82.9 (7.9), C: 84.1 (7.5) Number recruited: hospital at home: 56; inpatient: 53
Interventions	Hospital at home run by S. Giovanni Battista Hospital, Turin, Italy: GHHS, patients referred from emergency department. 24-hour-a-day care available, home nursing multidisciplinary care, rapid access to equipment.
Outcomes	Behavioural disturbances, number of patients treated with antipsychotic drugs on admission and on discharge, mortality, length of stay, place of discharge (home or to a nursing home)
Notes	Follow-up: to discharge from service 4 participants admitted from hospital at home to hospital for new medical problems. Funding: not reported Conflicts of interest: not reported Ethical approval: not reported

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Random sequence generation not described

Admission avoidance hospital at home (Review)

Tibaldi 2004 (Continued)

Allocation concealment (selection bias)	Unclear risk	Allocation concealment not described
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for cognitive status, severity of disease, and activities of daily living; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	Assessment method not reported
Blinding of outcome assessment (detection bias) Objective outcomes	Unclear risk	Low risk for mortality
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Withdrawals not reported
Selective reporting (reporting bias)	Unclear risk	Insufficient information to allocate low or high risk

Tibaldi 2009
Study characteristics

Methods	Parallel randomised trial Study conducted between April 2004 and April 2005.
Participants	Setting: Italy People with acute decompensation of chronic heart failure recruited within 12 to 24 hours of admission to the emergency department. Care supervision possible at home, telephone at home, need for IV infusions, living in catchment area, at least 1 previous admission for chronic heart failure Age: 75 years and over, mean age 81 Number recruited: hospital at home: 48; hospital: 53
Interventions	Admission avoidance hospital at home, hospital outreach (hospital maintains legal and financial responsibility); 24-hour care available 7 days a week; 4 specialist geriatricians, home care nurses, physiotherapist, social worker, counsellor, IV infusions available. Control group: admission to San Giovanni Battista Hospital, Turin, Italy
Outcomes	Mortality, readmission, length of stay, residential care, health status, psychological well-being
Notes	Funding: not reported

Admission avoidance hospital at home (Review)

Tibaldi 2009 (Continued)

Conflicts of interest: none reported

Ethical approval: hospital ethics committee

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Computer-generated random sequence
Allocation concealment (selection bias)	Low risk	Numbered, sealed envelopes
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for health status and psychological well-being; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Low risk	Outcomes assessed by a postgraduate doctor not involved with delivery of health care, and blinded to the study allocation
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Outcomes assessed by a postgraduate doctor not involved with delivery of health care, and blinded to the study allocation
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	4% loss to follow-up
Selective reporting (reporting bias)	Low risk	Standard set of outcomes reported

Vianello 2013

Study characteristics

Methods	Parallel randomised trial Study conducted between January 2009 and December 2011.
Participants	Setting: Italy Patients with neuromuscular disease and who had an acute respiratory tract infection and required hospital admission; recruited between January 2009 and December 2011. Number recruited: hospital at home: 26; inpatient hospital: 27
Interventions	The use of a portable ventilator; a respiratory therapist made daily visits for the first 3 days of home care, and district nurses and caregivers were trained in the application of the device and on assisting

Admission avoidance hospital at home (Review)

Vianello 2013 (Continued)

with coughing. District nurses visited daily until recovery from the respiratory tract infection, participants also had telephone access to pulmonary specialists.

Outcomes	Recovery from exacerbation, defined as relief of respiratory distress and return of SpO ₂ level
Notes	<p>Follow-up: 3 months</p> <p>Funding: Associazione Distrofia Muscolare, Associazione Sclerosi Laterale Amiotrofica, and Unione Italiana Lotta Alla Distrofia Muscolare (Italy)</p> <p>Conflicts of interest: none reported</p> <p>Ethical approval: institutional review board ethics committee</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Method not reported
Allocation concealment (selection bias)	Unclear risk	Not reported
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for respiratory distress and SpO ₂ level; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Blinding of participants and personnel not possible
Blinding of outcome assessment (detection bias) Subjective outcomes	Unclear risk	Subjective outcomes not reported
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for mortality, need for intubation, and cost
Incomplete outcome data (attrition bias) All outcomes	Low risk	Follow-up data reported in Table 3, page 2066; the authors did not report loss to follow-up
Selective reporting (reporting bias)	Unclear risk	Insufficient information to allocate low or high risk

Wilson 1999
Study characteristics

Methods	Parallel randomised trial
---------	---------------------------

Admission avoidance hospital at home (Review)

Wilson 1999 (Continued)

Study conducted between November 1995 and May 1997.

Participants	<p>Setting: UK</p> <p>Patients with a mix of conditions (majority elderly) referred by GP to Bed Bureau</p> <p>Number recruited: hospital at home: 102; inpatient: 97</p> <p>6 patients refused hospital at home care and were admitted to hospital.</p>
Interventions	<p>Hospital at home (admission avoidance)</p> <p>Type of service: multidisciplinary team (nurses, therapy, generic health workers, cultural link worker)</p> <p>Referred by a GP, who maintains medical responsibility</p> <p>Maximum of 5 patients at a time</p> <p>Control group: inpatient hospital care</p>
Outcomes	Mortality, readmission, functional status, quality of life, patient satisfaction
Notes	<p>Follow-up: 3 days, 2 weeks, 3 months</p> <p>Funding: National R&D Programme, Primary-Secondary Care Interface, NHS Executive, North Thames (UK)</p> <p>Conflicts of interest: none reported</p> <p>Ethical approval: local ethics committee</p> <p>This author contributed IPD for a previous update of this review (Shepherd 2016a).</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Block randomisation
Allocation concealment (selection bias)	Low risk	Consecutively numbered, sealed envelopes
Baseline outcome measurements (selection bias)	Low risk	Baseline outcome measurements done prior to intervention for functional status and quality of life; no relevant differences found
Baseline characteristics (selection bias)	Low risk	Baseline characteristics of the study and control groups are reported and are similar
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Outcome assessments by independent research staff, decision to admit made by hospital staff, not research team
Blinding of outcome assessment (detection bias) Subjective outcomes	Low risk	Low risk for health status (Sickness Impact Profile 68), cognitive function (Clifton Assessment Procedures for the Elderly), functional status (Barthel Index), and quality of life (EuroQol)
Blinding of outcome assessment (detection bias) Objective outcomes	Low risk	Low risk for mortality, readmission, resource use and cost

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Cabrol 2000	Compares inpatient and outpatient (ambulatory) treatment
Duiverman 2019	Tests the feasibility of home initiation of chronic non-invasive ventilation to ameliorate chronic respiratory failure at home, using telemedicine
Hazenberg 2014	Tests the feasibility of introducing technologies that ameliorate chronic respiratory failure, at home. For such patients initiation of the treatment has normally been in hospital, but may be feasible and safe at home.
Hill 1978	Patients with myocardial infarction are not suitable to be treated at home because they require urgent treatment (www.nhs.uk/conditions/heart-attack/treatment/).
King 2000	Cross-over randomised controlled trial evaluating chemotherapy provided in a home setting versus an outpatient clinic setting
Levine 2021	Remote physician care versus daily in-person physician hospital at home, with no hospital comparison
Mascardi 2016	Tests the feasibility of introducing technologies that ameliorate chronic respiratory failure, at home. For such patients initiation of the treatment has normally been in hospital, but may be feasible and safe at home.
Mather 1976	Patients with myocardial infarction are not suitable to be treated at home because they require urgent treatment (www.nhs.uk/conditions/heart-attack/treatment/).

Admission avoidance hospital at home (Review)

Study	Reason for exclusion
NCT02363413	Tests the feasibility of introducing technologies that ameliorate chronic respiratory failure, at home. For such patients initiation of the treatment has normally been in hospital, but may be feasible and safe at home.
NCT03490084	Not randomised
Wade 1985	Clinical controlled trial Compared 2 districts, 1 with a domiciliary stroke service and 1 without
Wolfe 2000	Intervention does not substitute for inpatient care.

Characteristics of ongoing studies [ordered by study ID]

[NCT03156686](#)

Study name	SAFETY and Efficacy of HOME-based hospitalization versus inpatient care for patients with acute heart failure in chronic heart failure. (SAFE-HOME)
Methods	Parallel randomised trial
Participants	Inclusion: adults aged ≥ 18 years diagnosed with acute heart failure, eligible for hospital home within 4 days of hospitalisation, affiliated with social security and complementary health insurance Exclusion: severe cognitive or behavioural disorders, no caregiver, other chronic conditions
Interventions	Intervention: home-based hospitalisation with intravenous diuretics Comparison: usual hospital care
Outcomes	Main outcome: time to rehospitalisation (3 months) Other outcomes: adverse events, quality of life, nutritional status, mortality, cost-effectiveness, time to rehospitalisation (12 months) Follow-up: 3 and 12 months
Starting date	June 2017
Contact information	Thibaud Damy, Hôpital Henri Mondor, France
Notes	

[Pouw 2018](#)

Study name	Hospital at home care for older patients with cognitive impairment and an acute medical illness
Methods	Parallel randomised trial
Participants	Inclusion: adults aged ≥ 65 who present to the emergency department with a defined acute illness; diagnosed with dementia, delirium, or other cause of cognitive impairment; caregiver present, living within the catchment area, and with adequate living arrangements

[Admission avoidance hospital at home \(Review\)](#)

Pouw 2018 (Continued)

	Exclusion: hospitalised during the previous 7 days, nursing home residents or awaiting a placement, need for palliative care, other acute or chronic conditions
Interventions	Intervention: hospital-level care provided at the patient's own home Comparison: usual hospital care
Outcomes	Main outcomes: mortality, institutionalisation, ADL-functioning, prevalence of hospital-associated geriatric syndromes, length of stay in hospital or in hospital at home care programme, contact with healthcare professionals Other outcomes: time spent at home (home-time), total number of days alive and out of the hospital or a skilled nursing facility, costs Follow-up: 6 months
Starting date	December 2017
Contact information	Maike A Pouw Department of Geriatrics, University Medical Center Groningen, University of Groningen, Groningen, the Netherlands
Notes	Trial registry: NTR6581

ADL: activities of daily living

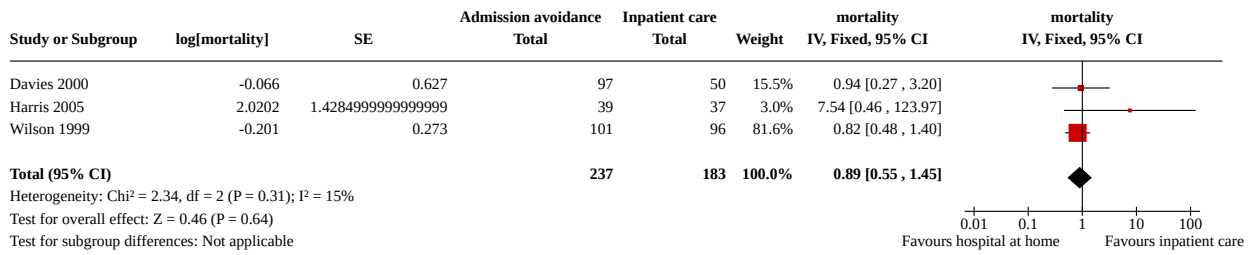

DATA AND ANALYSES
Comparison 1. Admission avoidance hospital at home versus inpatient care

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.1 Mortality at 3 months using IPD	3	420	mortality (IV, Fixed, 95% CI)	0.89 [0.55, 1.45]
1.2 Mortality at 6 months' follow-up (using published data, and IPD from Wilson and Sheperd)	5	1502	Risk Ratio (IV, Fixed, 95% CI)	0.88 [0.68, 1.13]
1.3 Readmission to hospital after discharge from hospital at home or inpatient care (3 to 12 months' follow-up)	8	1757	Risk Ratio (IV, Fixed, 95% CI)	1.14 [0.97, 1.34]
1.3.1 Readmission for older patients with a medical condition using IPD and published data. N=1856	8	1757	Risk Ratio (IV, Fixed, 95% CI)	1.14 [0.97, 1.34]
1.4 Transfer to hospital while receiving hospital at home	0		Other data	No numeric data
1.5 Living in residential care at follow-up	4	1271	Risk Ratio (IV, Fixed, 95% CI)	0.53 [0.41, 0.69]

Admission avoidance hospital at home (Review)

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.5.1 With a medical condition (6 months' follow-up)	4	1271	Risk Ratio (IV, Fixed, 95% CI)	0.53 [0.41, 0.69]
1.6 Quality of life/health status	9		Other data	No numeric data
1.6.1 Admission avoidance quality of life	9		Other data	No numeric data
1.7 Functional status	10		Other data	No numeric data
1.7.2 Admission avoidance patients with a medical condition - functional ability	10		Other data	No numeric data
1.8 Psychological health	7		Other data	No numeric data

WHAT'S NEW

Admission avoidance hospital at home (Review)

Copyright © 2024 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

Date	Event	Description
24 February 2022	New citation required but conclusions have not changed	We identified four new trials in this update (Echevarria 2018 ; Levine 2018 ; Levine 2020 ; Shepperd 2021).
24 February 2022	New search has been performed	New searches performed, four new trials added to the review. The review now includes 20 trials. In this update we removed data reported by Kalra 2000 and Ricauda 2004 from the meta-analysis, as evidence recommends that people with a suspected stroke be directly admitted to a specialist acute stroke unit after initial assessment (Langhorne 2020 ; Langhorne 2021). An acute stroke unit is a discrete area in the hospital that is staffed by a specialist stroke multidisciplinary team, with access to equipment for monitoring and rehabilitating patients (NICE 2019).

HISTORY

Review first published: Issue 4, 2008

Date	Event	Description
6 July 2011	Amended	Reference revised to published review.
8 June 2011	Amended	Title changed for consistency and changes to published notes.
17 February 2010	Amended	Change to published notes.
1 August 2008	New search has been performed	This review is an updated search and partial update from the original review (Shepperd 1998). Shepperd 1998 has been split into three reviews, of which this is one.
10 July 2008	Amended	Converted to new review format.

CONTRIBUTIONS OF AUTHORS

KE screened records, extracted data, assessed risk of bias, analysed the results for this update, and contributed to the writing of the review.

SI screened records, extracted data, and commented on each draft of the review.

HD and MJC contributed to the interpretation of data and writing of the review for the 2008 update.

DGB screened records, extracted data, and contributed to the writing of the review.

EW commented on the drafts and final draft of the review.

SS co-ordinated the review, screened records, extracted data, analysed the results (with HD) for the 2008 update with individual patient data, and led the writing of the review. SS did not assess risk of bias or extract data from the [Shepperd 2021](#) study.

DECLARATIONS OF INTEREST

KE: none known.

SI: none known.

HD: none known.

MC: is a Cochrane Editor, but was not involved in the editorial process of this review.

Admission avoidance hospital at home (Review)

DGB: is a Cochrane Editor, but was not involved in the editorial process of this review.

EW: no declarations of interest.

SS is author of one of the included studies ([Shepperd 2021](#)); she did not perform risk of bias assessment, data extraction, or GRADE assessment for that study. SS is a Cochrane Editor, but was not involved in the editorial process of this review.

SOURCES OF SUPPORT

Internal sources

- Nuffield Department of Population Health, University of Oxford, UK
Sasha Shepperd

External sources

- National Institute for Health and Care Research (NIHR), UK

Funding from the National Institute for Health and Care Research (NIHR), via Cochrane Infrastructure funding to the EPOC Group supported the conduct of this review, the views and opinions expressed therein are those of the authors and do not necessarily reflect those of the National Institute of Health Research or the Department of Health and Social Care. A previous version of the review was supported by an NIHR Research Scientist in Evidence Synthesis Award to Sasha Shepperd.

- The Healthcare Improvement Studies Institute (THIS), UK

Kate Edgar is funded by THIS Institute as part of a doctoral fellowship. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of The Healthcare Improvement Studies Institute.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

We updated the methods to align with current Cochrane guidance ([MECIR 2012](#)).

NOTES

This review is the fourth update; the original review was first published in Issue 1, 1998 of the Cochrane Library ([Shepperd 1998](#)). The original review has been separated into three distinct reviews: Hospital at home admission avoidance, Hospital at home early discharge, and Hospital at home: home-based end-of-life care. The titles have been changed for consistency. Hospital at home early discharge, [Gonçalves-Bradley 2017](#), and Hospital at home: home-based end-of-life care, [Shepperd 2016b](#), are published in the Cochrane Library.
