

Supporting information

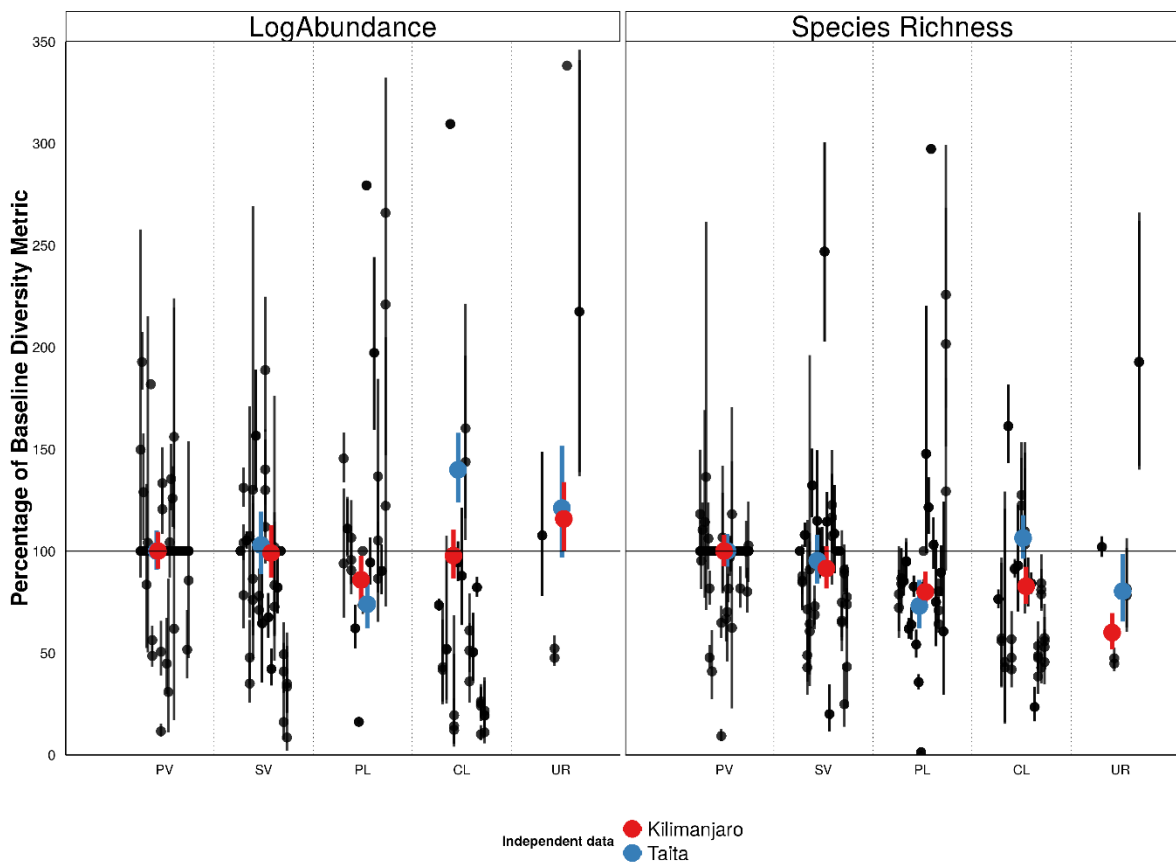

Figure S1: For the broad-scale dataset (black points) and the field sites (coloured points), the relative species richness and abundance values (compared to primary vegetation as a baseline) of all land uses for each individual study. The figure shows that our field-study estimates are always within the range of modelled study-level estimates in the broad-scale dataset. Land-use categories are primary vegetation (PV), secondary vegetation (SV), plantation forest (PL), cropland (CL) and urban (UR).

Table S1: Full list and description of studies in the broad-scale dataset. Studies that looked at multiple taxonomic groups were split into individual studies for the analysis.

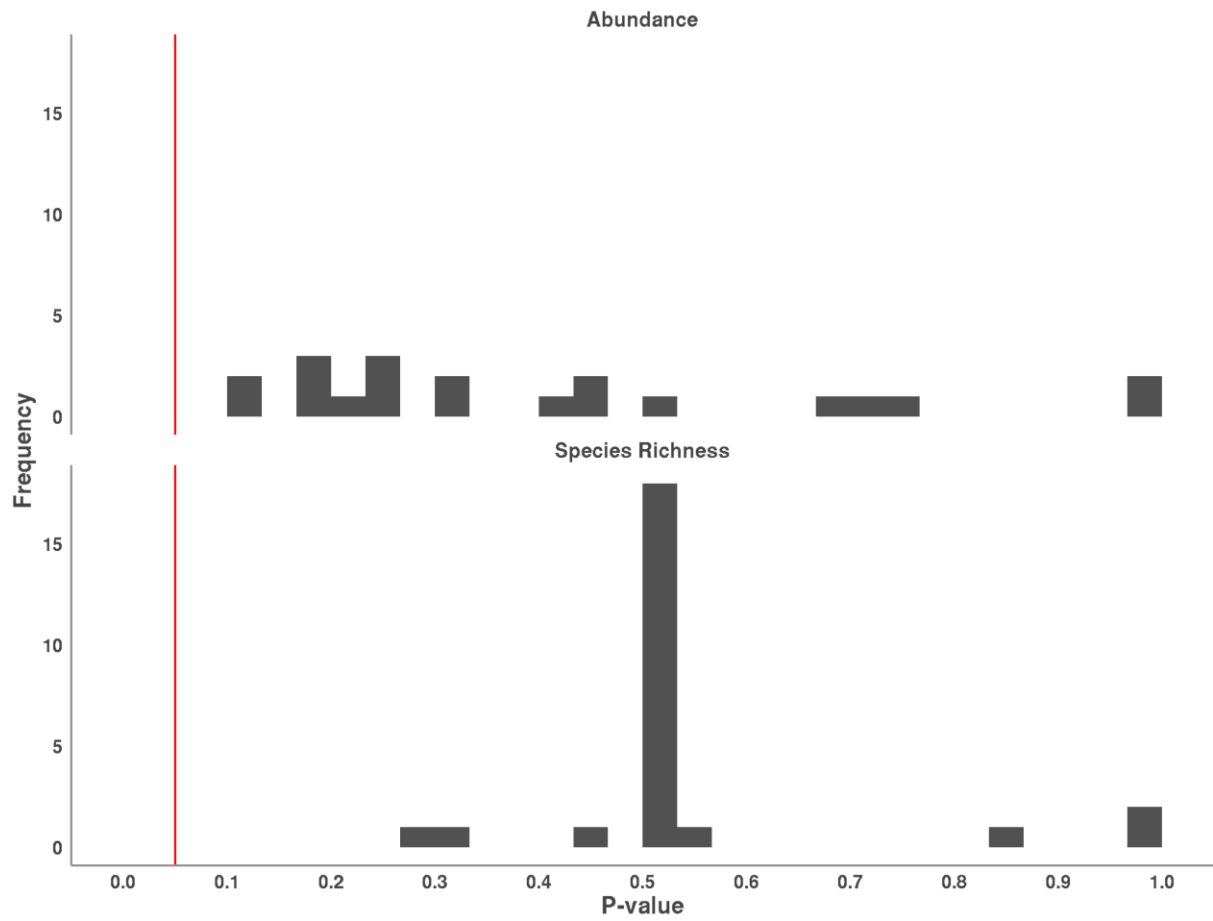

Figure S2: Tests for spatial autocorrelation within the model residuals, showing the distribution of P-values from sets of Moran's tests on the residuals associated with each individual study. Significant autocorrelation ($P < 0.05$) is indicated by the vertical red line.

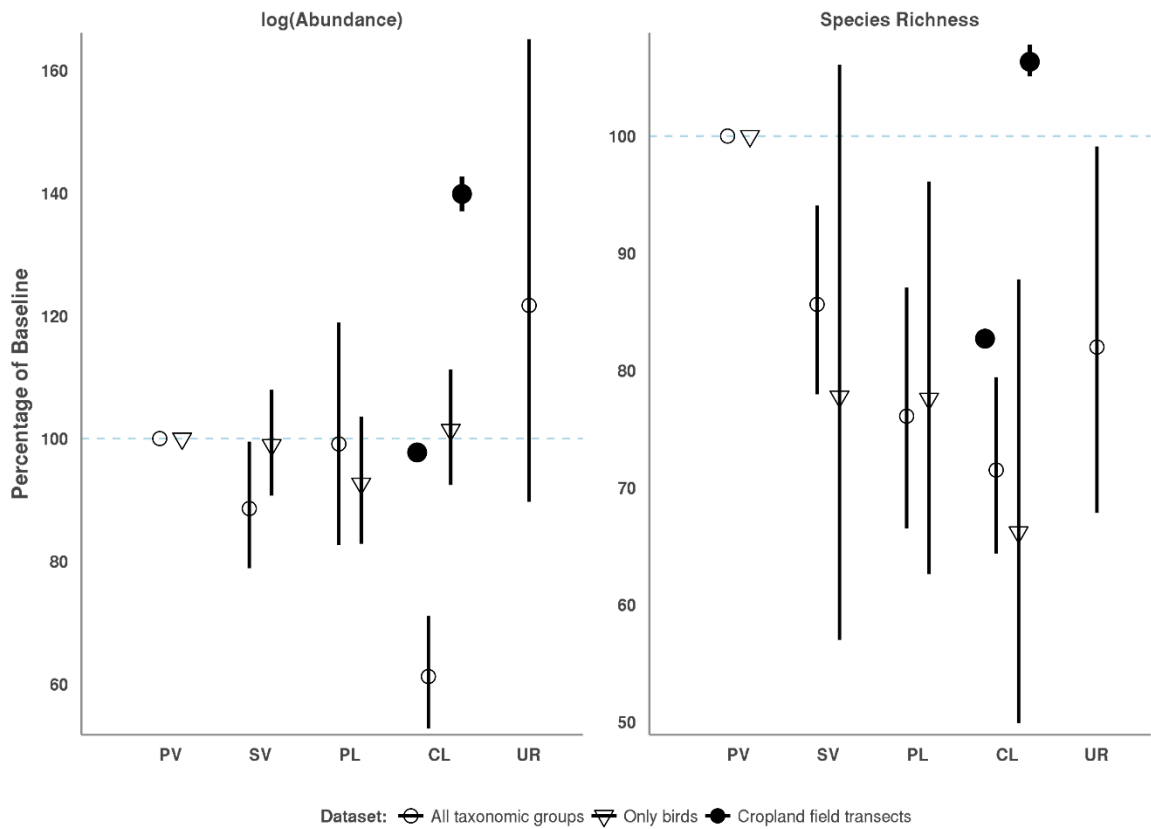

Figure S3: The response of species richness and total abundance to land use, from the Africa-wide model (open symbols) and the independent field data for cropland (closed symbols). Here, the Africa-wide models are shown for all taxonomic groups (open circles) and for birds only (open triangles). Land-use categories are primary vegetation (PV), secondary vegetation (SV), plantation forest (PL) and cropland (CL). There is no urban category (UR) for comparison as there were insufficient numbers of urban sites in the broad scale dataset for birds. All values are expressed as the percentage of the baseline values in primary vegetation. Error bars show one standard error.

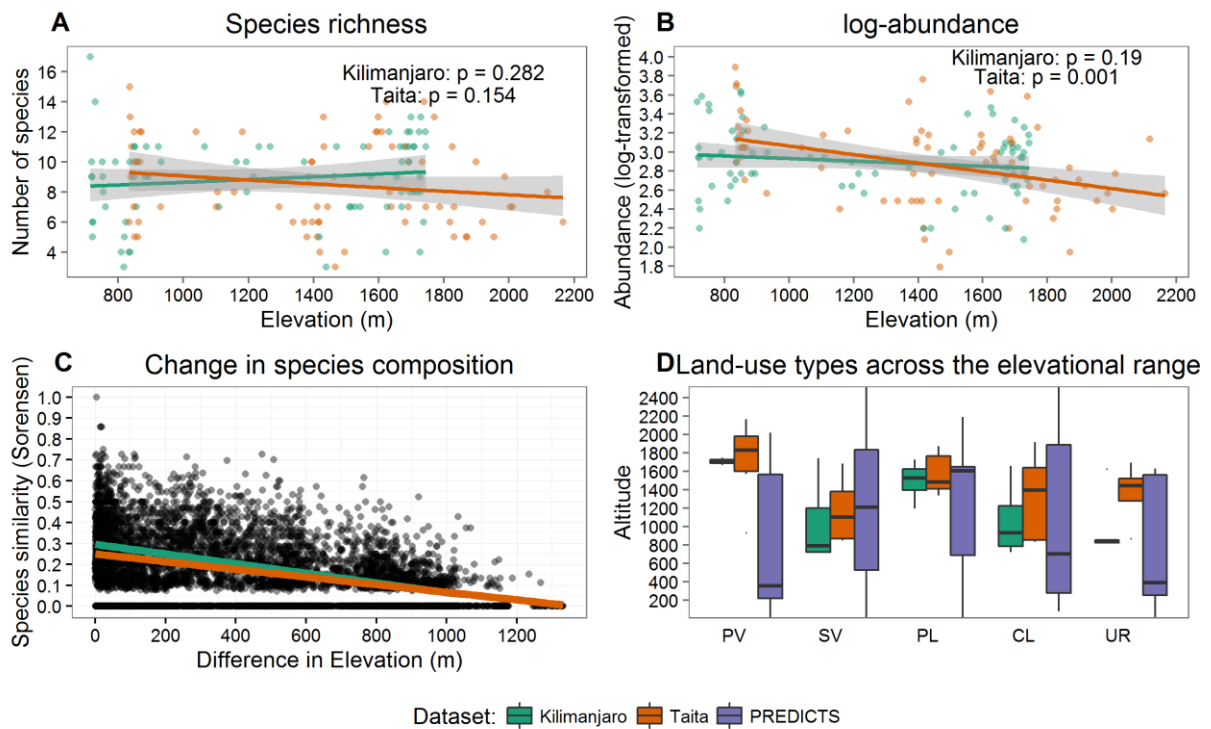

Figure S4: Effect of elevation (in m) on species richness, log-abundance and species composition for our independent field sites at Taita and Kilimanjaro. Generalized linear model with Poisson errors (for Species richness) and Gaussian errors (for log-abundance) were fitted independently for each transect. Changes in composition were assessed as Sorensen similarity index between all pairs of sites and fitted against the absolute difference in elevation between sites using generalized linear models with Gaussian errors. **(A)** There was no significant effect of elevation on species richness for either transect, but there was a significant effect for log-abundance in the Taita Hills **(B)**. **(C)** Species assemblage similarity decreases with elevational differences between sites. **(D)** Distribution of the land-use classes of our independent sites across the elevational range of both study transects. Land use abbreviations as in Figure S1.

Table S2: The PREDICTS project (Hudson et al., 2014, www.predicts.org.uk) land use and land-use intensity matrix to which all study sites have been classified.

	Minimal use	Light use	Intense use
Primary forest (forest composed of native vegetation, which is not known to have been destroyed during historical times)	Any threats identified are very minor (e.g., very light use) or very limited in the scope of their effect (e.g., hunting of a particular species of limited ecological importance).	One or more threats of moderate intensity (e.g., selective logging) or breadth of impact (e.g., bushmeat extraction), which are not severe enough to markedly change the nature of the ecosystem.	One or more threats that is severe enough to markedly change the nature of the ecosystem (e.g., clear-felling).
Primary Non-Forest (native vegetation, which has not been destroyed recently enough for there to be any discernible impact on vegetation architecture)	Any threats identified are very minor (e.g., very light use) or very limited in the scope of their effect (e.g., hunting of a particular species of limited ecological importance).	One or more threats of moderate intensity (e.g., selective logging) or breadth of impact (e.g., bushmeat extraction), which are not severe enough to markedly change the nature of the ecosystem.	One or more threats that is severe enough to markedly change the nature of the ecosystem (e.g., clear-felling).
Mature Secondary Vegetation (previously destroyed vegetation recovering to natural state rather than being managed to maintain it in a non-natural state; architecture, if not diversity, approaching original complexity)	As for Primary Vegetation-Minimal use	As for Primary Vegetation-Light use	As for Primary Vegetation-Intense use
Intermediate Secondary Vegetation (previously destroyed vegetation recovering to natural state rather than being managed to maintain it in a non-natural state; mixed architecture or mid-successional stage of recovery)	As for Primary Vegetation-Minimal use	As for Primary Vegetation-Light use	As for Primary Vegetation-Intense use
Young Secondary Vegetation (previously destroyed vegetation recovering	As for Primary Vegetation-Minimal use	As for Primary Vegetation-Light use	As for Primary Vegetation-Intense use

to natural state rather than being managed to maintain it in a non-natural state; mainly ruderal species and simple architecture; early-successional stage)			
Secondary Vegetation (indeterminate age) (previously destroyed vegetation recovering to natural state rather than being managed to maintain it in a non-natural state; age indeterminate)	As for Primary Vegetation-Minimal use	As for Primary Vegetation-Light use	As for Primary Vegetation-Intense use
Plantation forest	Extensively managed or mixed timber, fruit/coffee, oil-palm or rubber plantations in which native understorey and/or other native tree species are tolerated, which are not treated with pesticide or fertiliser, and which are not clear-felled.	Monoculture fruit/coffee/rubber plantations with limited pesticide input, or mixed species plantations with significant inputs. Monoculture timber plantations of mixed age with no clear-felling. Monoculture oil-palm plantations with no clear-felling.	Monoculture fruit/coffee/rubber plantations with significant pesticide input. Monoculture timber plantations with similarly aged trees or timber/oil-palm plantations with extensive clear-felling.
Cropland	Low-intensity farms, typically with small fields, mixed crops, crop rotation, little or no inorganic fertiliser use, little or no pesticide use, little or no ploughing, little or no irrigation, little or no mechanisation.	Medium intensity farming, typically showing some but not many of the following: large fields, annual ploughing, inorganic fertiliser application, pesticide application, irrigation, no crop rotation, mechanisation, monoculture crop. Organic farms in developed countries often fall within this category, as may high-intensity farming in developing countries.	High-intensity monoculture farming, typically showing many of the following features: large fields, annual ploughing, inorganic fertiliser application, pesticide application, irrigation, mechanisation, no crop rotation.
Pasture	Pasture with minimal input of fertiliser and pesticide, and with low stock density	Pasture either with significant input of fertiliser or pesticide, or with high stock density	Pasture with significant input of fertiliser or pesticide, <i>and</i> with high stock density (high enough to cause significant

	(<i>not</i> high enough to cause significant disturbance or to stop regeneration of vegetation).	(high enough to cause significant disturbance or to stop regeneration of vegetation).	disturbance or to stop regeneration of vegetation).
Urban	Extensive managed green spaces; villages.	Suburban (e.g. gardens), or small managed green spaces in cities.	Fully urban with no significant green spaces.

Table S3: Full model selection table for (log-transformed) abundance. All possible combinations of land use (PREDICTS.LU), land-use intensity (PREDICTS.LUI) Land use/Land-use intensity interaction (LUInter), log-transformed human population density (logpop), forest cover (FC2000), elevation (elev), mean NDVI (meanNDVI) and vegetation offtake (yield.ndvi.corr) were fitted. Shown are the model covariates, the parameter count (K), AIC, delta AIC, the Model likelihood (ModelLik), AIC weights (AICWt), log-likelihood (LL) and cumulative AIC weights (Cum.Wt). ModelLik and AICwt are rounded to the fifth decimal for visual display.

Table S4: Full model selection table for species richness. All possible combinations of land use (PREDICTS.LU), land-use intensity (PREDICTS.LUI) Land use/Land-use intensity interaction (LUInter), log-transformed human population density (logpop), forest cover (FC2000), elevation (elev), mean NDVI (meanNDVI) and vegetation offtake (yield.ndvi.corr) were fitted. Shown are the model covariates, the parameter count (K), AIC, delta AIC, the model likelihood (ModelLik), AIC weights, log-likelihood (LL) and cumulative AIC weights (Cum.Wt). ModelLik and AICwt are rounded to the fifth decimal for visual display

Model covariates	K	AIC	Delta AIC	ModelLik	AICWt	LL	Cum.Wt
