Talk outline

- A V1 model to study contextual influences.
- How contextual influences affect responses to a grating patch.
- Dependence on size of grating — summation zone, suppression zone, (Sceniak et al 1999), and, additionally, the **second rise, and more.**
- Relation with figure-ground effects, and visual behavior/computation.

The V1 model and its function

Input: bar's contrast

Output depends on

(1) the bar's contrast;

(2) the bar's context;

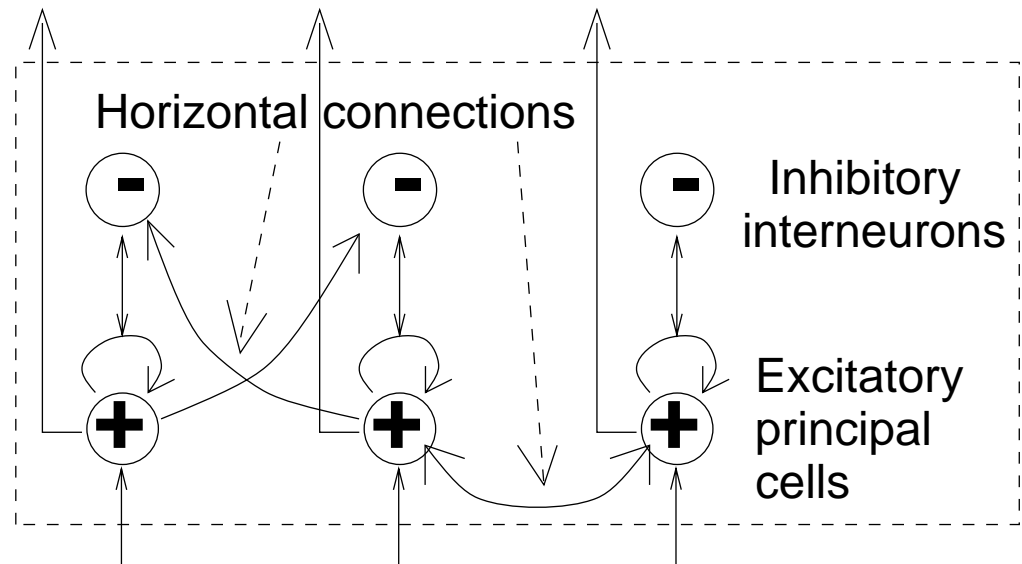

highlighting where homogeneity breaks down

Model output

Outputs to higher visual areas

The model

Visual inputs, filtered through the receptive fields, to the excitatory cells.

Input to model

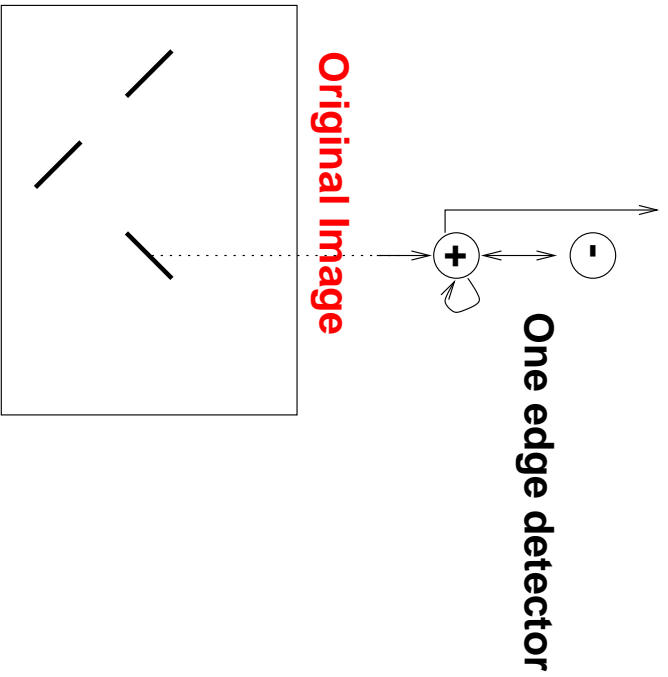

Units representing the edges are excited. Units representing edges form a network

Sampled image in cortex

Sampled by edge detectors

finding 3 edges at different locations i, j, k , and orientations $\theta_i, \theta_j, \theta_k$

Model Schematic:

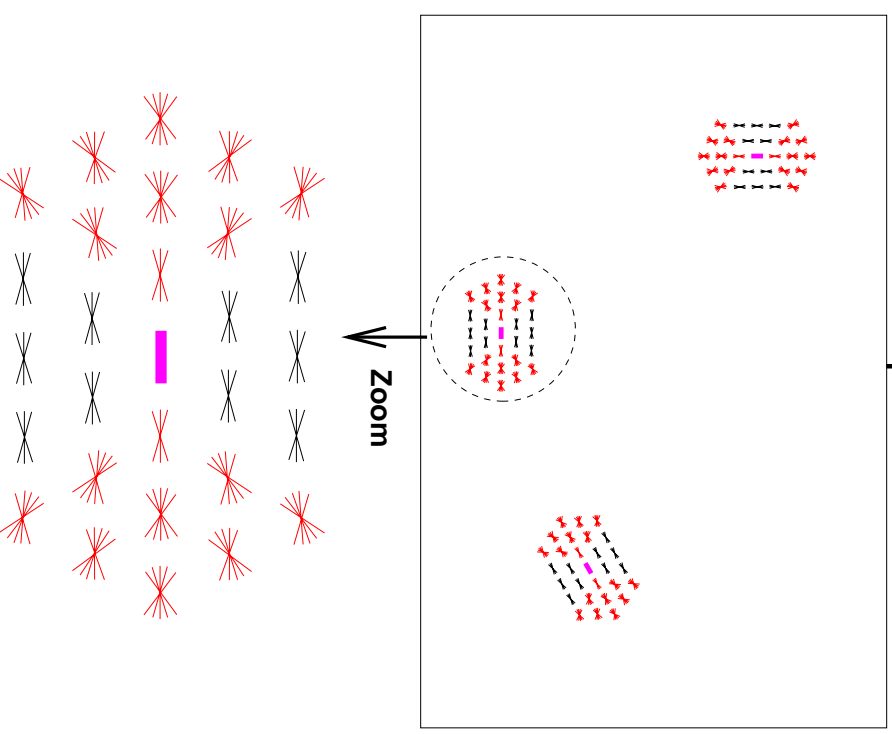

Intra-cortical Interactions

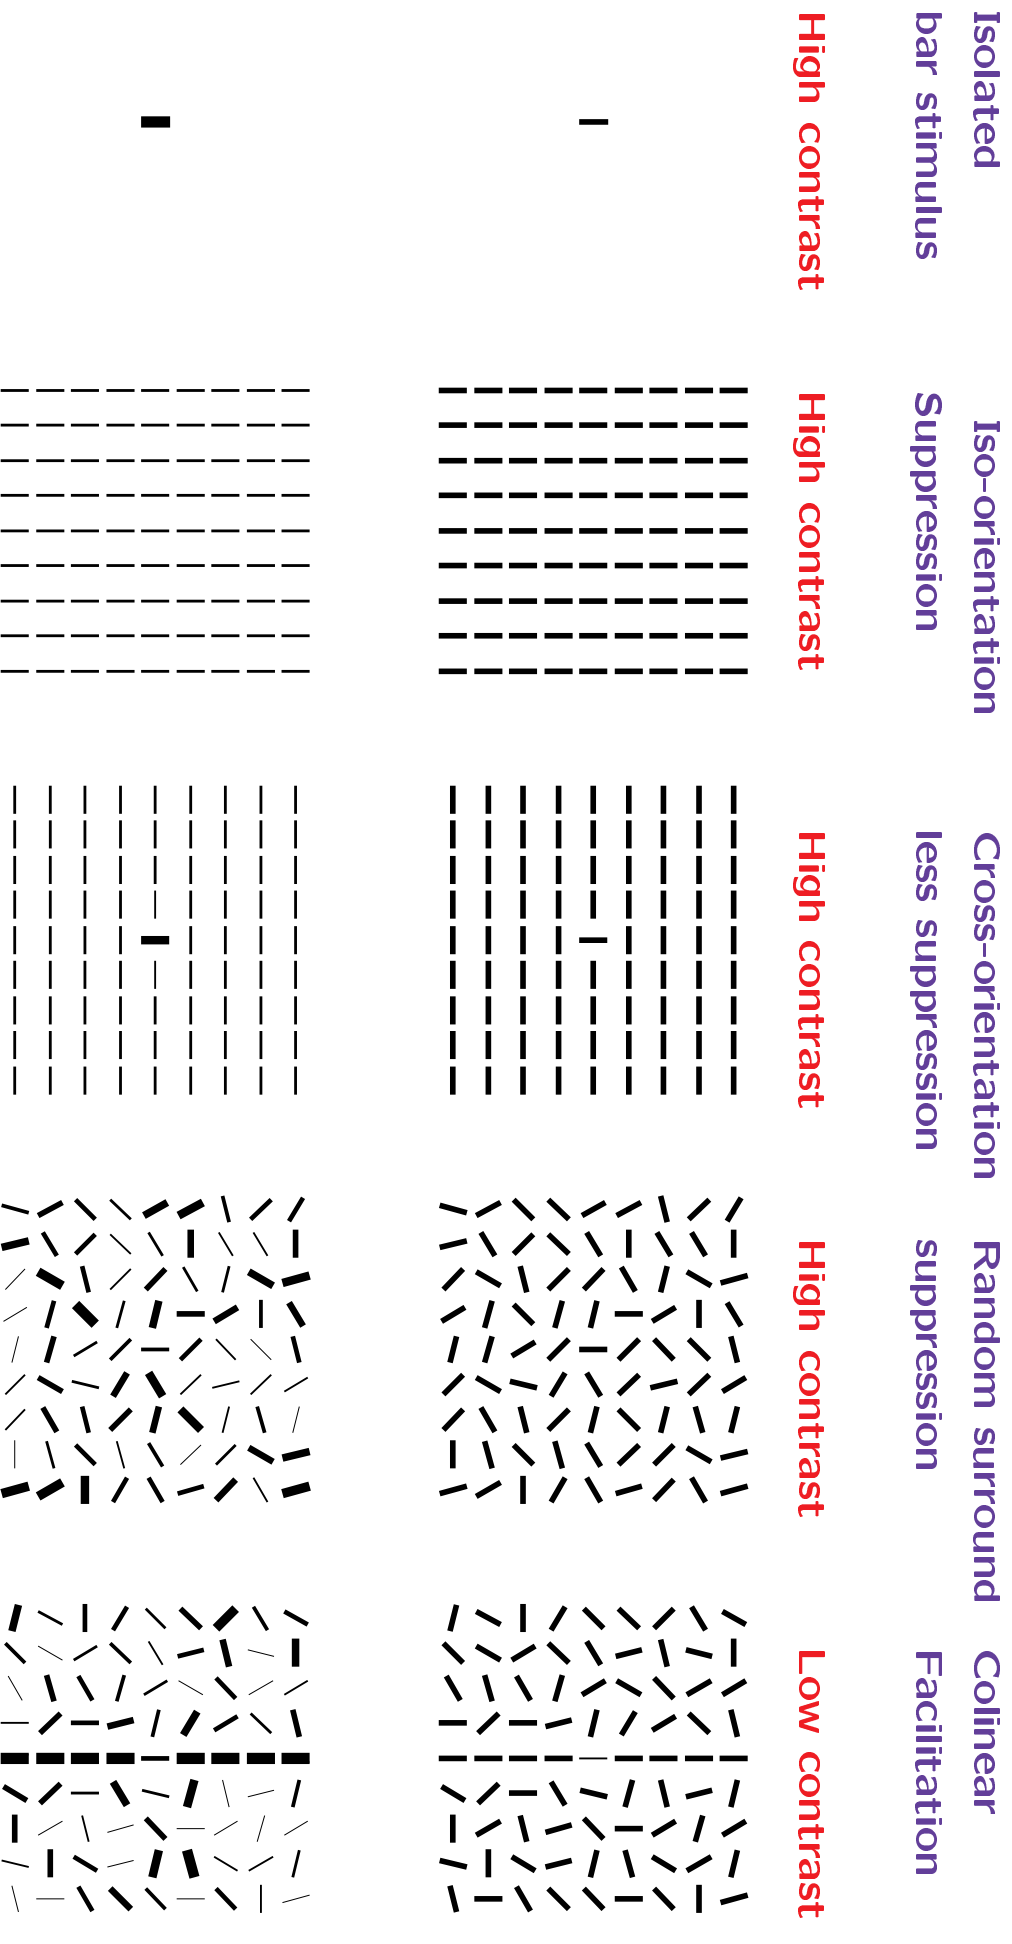

Computed image in cortex after cortical interactions

Interaction pattern

Model produces the usual contextual influences observed in V1

Another product of contextual influences:

The border effect, physiologically and in the model

Physiology

Model

border between two textures

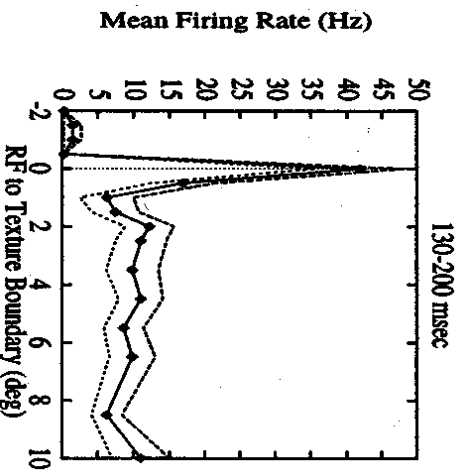

border between a texture and a blank

Input
blank
here

Cell responses

data from Lee et al. 1998

Also observed by Gallant et al. 1995

Note: The border region

The border suppression region

The secondary ripple.

What then should be the

Responses to a grating patch ? (cf. Sceniak et al 1999)

Direct input field vs Receptive field

Model Output

Model Output

As the grating patch increases, the response increases, decreases, and then, at an even larger grating size, **a second rise**.

Response to center of the grating patch

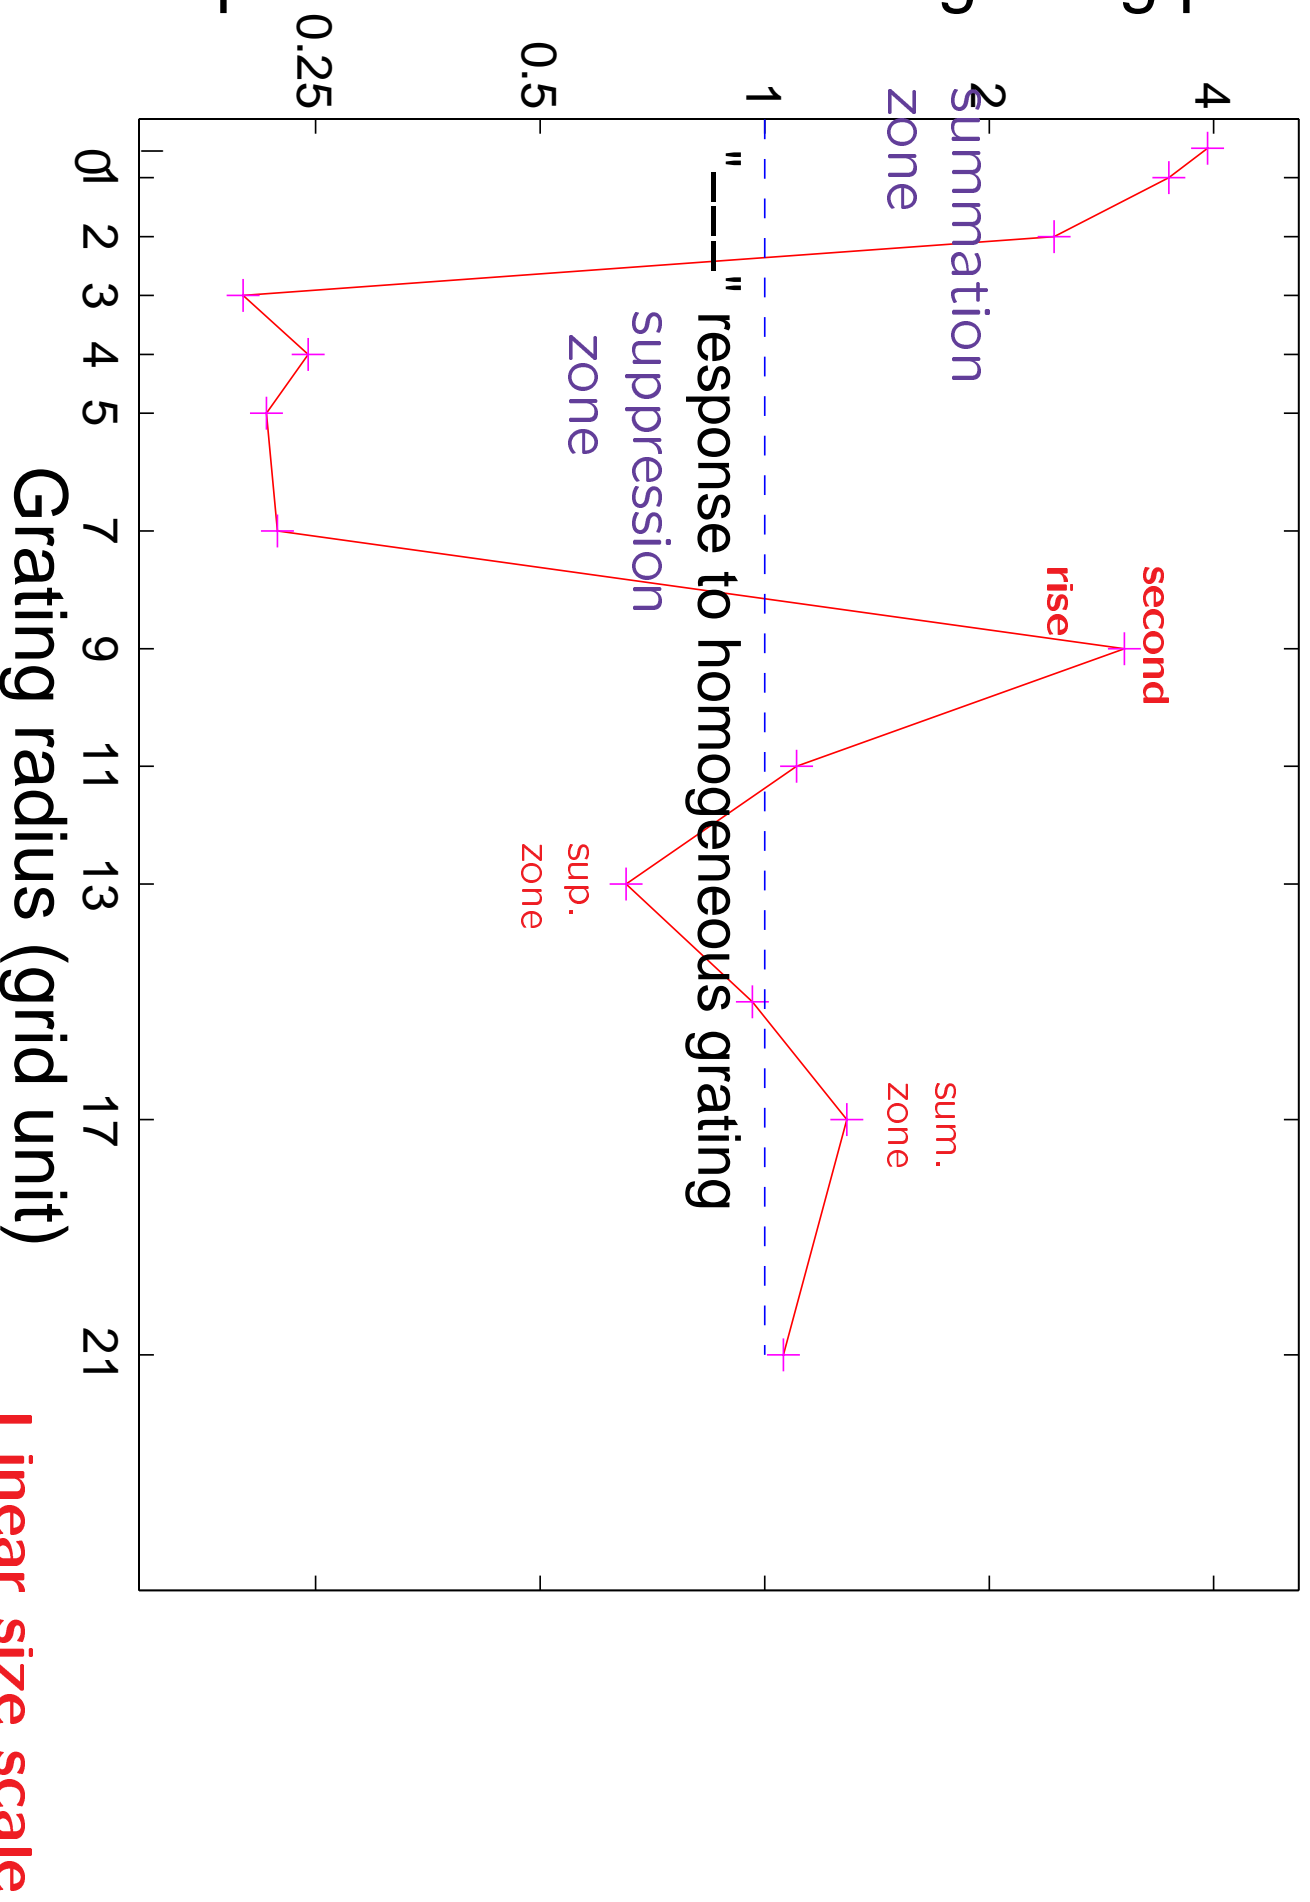

Summation zone/suppression zone, **second rise?**

Log size scale

Summation zone/suppression zone, second rise? .

Response to center of the grating patch

The second rise predicted can be tested easily physiologically.

There is an indirect physiological evidence

(courtesy of A.B. Bonds and J. Kabara, 2000):

Stimuli: center grating,
and a ring of outer grating.

Response to center vs. dR, etc.

jc.29.05

What if the grating patch is surrounded by an orthogonal background grating?

figure-ground

Usually, the general contextual suppression from the background grating reduces the responses to the center grating.

When the size of the figure grating is such that the center of the figure grating is in the border suppression region, suppression from background on the border of the figure grating disinhibits the figure center.

Cross-orientation facilitation observed by Sillito et al

happens when the figure center is in the border suppression region

Model Input

Model Output

The figure center is at the border suppression region

The center of figure is dis-inhibited by the background grating, which suppresses the figure border via general orientation unspecific suppression

Cross-orientation facilitation — dependence on the figure size

**Critical exp. parameter:
size of figure grating**

Explains why some did not observe this phenomena

Figure-ground effects”, “medial axis effects” observed physiologically

Higher responses to figure, its medial axis, than responses to grounds, observed by Lamme, Zipser, Lee, etc.

What can our model say about them?

data from Lee, Mumford, Romero, Lamme 1998

Model Input

Model Output

When the figure is the border region itself

The whole figure highlights, Observed by Lamme, Zipser, et al

Prediction:

“The figure ground effects”

(like those observed so far in V1)

When the figure center is at the border suppression region
The figure center suppressed

When the secondary ripples from both borders reinforce

The medial axis effect Observed by Lee et al 1998

When the figure is large enough

Figure ground effect diminish in figure center

- (1) depend on the figure size,
- (2) disappear for large figures,
- (3) are caused by the border effect.

- (4) could be accounted for by V1 mechanisms

(without resorting to feedback from higher visual centers)

Computational goal of contextual influences

Not simply to complicate the “receptive fields” .

Proposal: But to achieve pre-attentive segmentation or visual grouping (pop out), e.g., texture segmentation, contour integration, figure search among distractors.

Achieve global visual computation from local “classical receptive fields” and finite range intra-cortical interactions

Summary

Contextual influences could give more than a single summation and suppression zone to the “receptive field” .

Prediction: Multiple summation and suppression zones may exist beyond the inner zones.

Relates to other contextual effects: cross-orientation facilitation, figure-ground effects, with **testable predictions**.

Finite range contextual influences provide neural basis for global visual computation: pre-attentive segmentation and grouping.
